Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

NOTES.

COMMENCING a new volume of *The Electrician* this week, it may not be inappropriate to call attention to the main developments of electrical engineering which seem likely to take place in the immediate future. Some of these are foreshadowed in articles that are to be found in the present issue. The Thompson-Walker system of traction, for example, developing a device not altogether new, is one indication of a very widespread effort which is being made by engineers to provide an efficient and satisfactory substitute for the overhead trolley. Notwithstanding this, however, an enormous amount of trolley construction is being pushed forward in the provinces. In the Llandudno municipal electric supply works, described on a later page, we have an illustration of the belated adoption of electric lighting by many of the smaller local authorities in the United Kingdom—this arousing from prolonged apathy being, in not a few instances, stimulated by the prospect of an early advent of electric traction within their borders. On Wednesday next the electric light works at Folkestone will be inaugurated. Simultaneously with the commencement of the new volume comes the announcement of the opening of important extensions to the municipal electric supply works at Hull; while only last week we recorded still more extensive additions to the works at Belfast. Glasgow also is the scene of a vigorous extension of electric generating and distribution plant, as will be gathered from an article we publish this week. Indeed, in all directions the electric supply business is growing so rapidly that not a small part of the work of the near future must consist in extending works that have already been in operation for some time past.

A BLUE-BOOK of 580 pages has now been issued, containing the complete minutes of evidence taken before the Select Committee on Telephones, together with the Chairman's draft report and the final report. Having given an account of each day's proceedings during the course of the inquiry, and reprinted the report in full, commenting both on it and on the evidence, it is needless to give a further *resumé* here. One incident, which occurred during the discussion on the Chairman's draft report is, however, of interest to note. It was proposed by Mr. GRIFFITH-BOSCAWEN to recommend that local authorities should, on starting telephone exchanges, be given a guarantee that either their plant should be purchased at a fair valuation in 1911, or their licences extended beyond that date; the draft report, and subsequently the final report, recommended that these licences should expire in 1911, at the same time as the licence of the National Telephone Co. The Committee was evenly divided on this point, and the amendment defeated only by the casting vote of the Chairman. This is significant, as showing the disposition—or we might even say pre-disposition—of a large section of the Committee to favour municipal telephony even at the cost of inconvenience to the public. With the exception of two experts, whose position as independent consultants must naturally, if unconsciously, bias them towards independent telephony, none of the witnesses with practical experience in the establishment and management of telephone exchanges advocated the erection of municipal systems.

THE autumn session of the Institution of Mechanical Engineers was inaugurated at Westminster on Wednesday last, when Mr. W. E. LANGDON read his Paper on "Electric Installations for Lighting and Power on the Midland Railway, with notes on Power absorbed by Shafting and Belting." The communication elicited a most useful discussion, principally on the subject indicated by the latter part of the title. Electric driving of machine tools and mills was advocated by numerous speakers, the efficiency of ordinary shaft-and-belt transmission being stated to be as low as 28 per cent. at the Midland Railway workshops, and in many other places being no higher than 20 per cent. Considerable differences of opinion were expressed as to the relative advantages of separate-driving and group-driving. Mr. LANGDON advocates separate-driving wherever more than one horse-power is needed; but Mr. HARRIS and other speakers observed that questions of capital cost often rendered it inadvisable to use a

Digitized by Google

separate motor for each machine, even when these were of considerable size. Mr. JEREMIAH HEAD brought out an important aspect of the subject, when he said that the question was often not merely one of substituting electric for mechanical transmission between a main engine and a number of machines, but involved the much wider question as to the substitution of one system driven by a single efficient engine, in place of a number of isolated plants each driven by a separate, small and inefficient engine, and often by separate boilers.

AN unfortunate accident occurred at the Brighton electricity works on Thursday last week, causing an interruption of the supply from 9:10 to 9:30 p.m. A 220-kilowatt armature developed a sudden short-circuit in its windings, and for some unexplained reason all the dynamos running at the time immediately dropped their minimum cut-outs. As a consequence the whole supply of 9,000 amperes, which was going out at the time, was interrupted. Fortunately Thursday was "early closing night," so practically all the shops escaped inconvenience, and by a lucky chance two of the theatres were having voluntary intervals at the time. Nevertheless, private consumers must have suffered considerably.

THIS occurrence raises a point of immense importance to central station engineers. The practice at Brighton and at several of the largest supply stations in this country is to use no excess-current cut-outs between the dynamos and the 'bus bars, but only minimum cut-outs. On the face of it this system would appear to afford an absolute safeguard against exactly what occurred at Brighton. One can easily conceive that, if excess-current cut-outs or fuses were used in series with each dynamo, a certain sluggishness in the minimum cut-out, in the case of an armature short-circuit, would blow the excess-current cut-outs of all the other machines. But for all of the minimum cut-outs to act it was essential that the current from the dynamos must have been enormously *reduced*, and, as there was no storage battery across the mains to send a back current, the explanation can only be sought in the behaviour of the dynamos themselves. If it could be assumed that the short-circuit sufficed to pull the machines up "dead" for an instant, the cause of the phenomenon would be clear; but this hypothesis appears hardly a probable one. Yet the speed will have been enormously reduced, and the reaction of the large current started in the armatures will have tended to weaken the fields, and it is just conceivable that these two causes inter-acting may have reduced the E.M.F., and therefore the current, sufficiently to release the cut-outs before the cut-out of the disabled machine had cleared its contacts. Another fact, not yet mentioned, might, by a remote possibility, have contributed to the remarkable result. Two machines of a smaller size were also running in parallel with the others, these being provided with ordinary fuses and no minimum cut-outs. The fuses of these machines did not blow. It may be that the speed of these dynamos was less affected than that of the larger ones, and that their higher E.M.F. also contributed to lessen the current from the larger generators.

WHATEVER the explanation may be, the most important question is how a recurrence of such a mishap is to be guarded against. To replace the minimum cut-outs by return-current cut-outs would probably be effectual, but there seems to be a prejudice against their shunt-winding. To separately excite the dynamos might lessen the probability of such an accident, although it is not certain that it could be depended on as an absolute safeguard. For the present it is probable that engineers of large continuous-current stations will be content to tie up their minimum cut-outs, and insert in place of them extremely heavy excess cut-outs, until more light is thrown on the matter. Experiments with artificial short-circuits might settle the question, but the risk of their damaging the plant is probably prohibitive.

Accident on a Glasgow Electric Car.—Early yesterday morning the trolley-arm of a double decked car in Parliament-road, Glasgow, broke. There were 20 passengers on the top of the car at the time, but no injury was done.

Cable Interruptions.—	Date of Interruption.
Bissao—Bolama	Aug. 3, 1898
St. Louis and Noronha	Oct. 17, 1898
Gibraltar—Tangier	Oct. 18, 1898
Pernambuco—Ceara	Oct. 19, 1898

Opening of a New Electric Supply Station at Hull.—On Monday last, the 24th inst., the new station for the Kingston-upon-Hull municipal electric supply works, in Sculcoates-lane, was formally inaugurated by the mayor. We shall present our readers with a description of these works in an early issue.

Institution of Electrical Engineers.—The opening meeting of the session will be held on Thursday, November 10th, when a Paper will be read by Prof. Silvanus P. Thompson on "Rotatory Transformers." We learn that the annual dinner will take place in the Grand Hall of the Hotel Cecil on Wednesday, December 7th, and that the invitations are likely to be issued during the coming week.

The Northern Society of Electrical Engineers.—At the meeting of this society on Tuesday, Mr. J. S. Raworth, the president, occupied the chair, and there was a large attendance. It was announced that the Council had sent letters of condolence to the relatives of Dr. John Hopkinson and of Mr. James Morton. The president then delivered his address on "The Rapid Development of Electrical Engineering in the year 1898."

Interruptions to Supply.—At about half-past seven on Saturday evening the electric supply at Wolverhampton was interrupted for a couple of hours. We have not ascertained the cause of the interruption.——At the Crystal Palace theatre last Tuesday afternoon the electric light on the stage and auditorium went out in the middle of the last act of the play. This was probably owing to a local fuse blowing, as the lights in the main building were not affected.

Soft Coal Burning.—The publishers of the *Railway Master Mechanic*, of Chicago, have recently issued the fifth edition of a useful little brochure, entitled "Soft Coal Burning," by C. M. Higginson. While the writer lays no claim to having made any original discovery in the matter, he has collected in convenient form and compiled in intelligible language the results of practice and methods extending over a long period. Engineers who are desirous of obtaining information in regard to smokeless and economical combustion of soft or bituminous coal will find in this little pamphlet many hints and items of advice that should serve their purpose.

The Electrical Engineers Volunteers.—An order is issued in the *London Gazette* with relation to the certificates of efficiency to members of the corps of Electrical Engineers, Royal Engineers (Volunteers). A certificate of efficiency, according to Army Form E, has been added for captains and subalterns, and another for non-commissioned officers and men. The forms of certificate of efficiency for the volunteer divisions of Submarine Miners, Royal Engineers, have also been

Digitized by Google

amended with regard to the technical qualifications required for the "Test Examination Certificate for recruits before being classed as Trained men," and "the laying out of cables" is inserted in the qualifications required of "Trained men."

The Institution Articles of Association.—Notice has been given that a special general meeting of the Members only of the Institution of Electrical Engineers will be held at Victoria Mansions, 28, Victoria-street, London, S.W., on Wednesday next, Nov. 3rd, at 4 o'clock in the afternoon, for the purpose of considering, and if thought fit, of passing the following resolution:—

That the Articles of Association contained in the printed document submitted to the meeting, and, for the purpose of identification, subscribed by the Chairman thereof, be, and the same are hereby approved; and that such Articles of Association be, and they are hereby, adopted as the Articles of Association of the Institution; and that Article Number One do come into operation forthwith, and that the remaining Articles, numbered Two to Eighty, both inclusive, with the schedules thereto, do come into operation on and from Jan. 1, 1889.

Should the resolution be passed by the requisite majority, it will be submitted for confirmation as a special resolution to a second special general meeting of the members which will be subsequently convened.

The "Moheghan" Disaster and Magnetic Disturbance.—The suggestion which has been put forward that the "Mohegan" disaster was caused by disturbance of the compass, due to the existence of magnetic rocks in the neighbourhood, has elicited the following interesting letter from Prof. A. W. Rücker, which we extract from *The Times* of Monday last:—

As the suggestion that the wreck of the "Mohegan" may have been due to a local deviation of the compass is again referred to in a letter which appears in your columns to-day, you will perhaps allow me to point out that such deviations are more likely to occur on land, where the needle may be within a few feet of the disturbing cause, than at sea, where they must be separated by a greater or less depth of non-magnetic water. During the magnetic survey of the United Kingdom, carried out by Dr. Thorpe and myself, observations were made at 12 places in Cornwall. Of these Lizard Down, Porthallow, and Falmouth were the nearest to the scene of the disaster, and at all of them the deviation of the compass from the normal magnetic meridian was extremely small. The largest disturbance of this kind which was observed in Cornwall occurred at St. Levan, near the Land's End, and only amounted to 11min. of arc, or less than two-tenths of a degree. The largest disturbance of the dipping needle was at Mullion, and was only 14min.

It is true that it is not impossible that the compass of a ship in relatively deep water might be appreciably affected for a distance of three or four miles by a concealed centre of magnetic disturbance. The best-known case of this sort is that of Port Walcott in North-West Australia, which was fully described by Captain Creak in the *Philosophical Transactions* for 1896. In that case, however, a compass on the neighbouring coast was affected, not as in Cornwall to the extent of a few minutes of arc, but through a range of 10deg.

To the improbability of such a source of danger as that suggested having escaped the notice of naval surveyors in a district so well known as the neighbourhood of the Manacles, we must, therefore, add the improbability of a great magnetic focus existing near land on which the magnetic disturbances are as small as they are in Cornwall. It is, of course, possible that here and there in that county there may be centres of magnetic disturbance greater than any we discovered, but from evidence collected in districts, such as the West of Scotland, where magetic rocks abound, I have no hesitation in saying that in general such causes could not affect the compass of a ship at a distance of a couple of hundred yards, and that though cases such as that above referred to are known to which this generalisation does not apply their number is small.

The Institution of Junior Engineers.—In his presidential address to the members of this Institution, on the 21st inst., Sir William H. White compared the growth and development of civil engineering to that of a tree, whose roots strike deep and stretch far, while the trunk enlarges and strengthens, and the branches multiply in all directions. He continued:—

Modern engineering has many branches, starting from the trunk-idea of utilising the great forces of nature for the service of man. Its roots strike deep, and reach far in the fruitful soil of science, drawing thence renewed vitality and fresh ideas, with which to meet the heavier and more varied tasks imposed upon the engineer by the ever-increasing needs of civilised life. Apart from the aid of science the engineer could not have solved many of the problems presented to him. He now welcomes the mathematician, the chemist, and the physicist as essential and valued allies. Scientific method is becoming more and more established in engineering practice and in experimental research. There is no exclusion of engineers from the ranks of scientific men. And there are numerous instances of men distinguished no less as scientists than as engineers.

This led Sir William to a sympathetic reference to the loss sustained by science and engineering in the death of Dr. John Hopkinson, and to the generous gift bestowed by Mrs. Hopkinson to Cambridge University. After giving instances of cases in which research work undertaken originally for scientific purposes only had largely influenced engineering practice, the speaker expressed his approval of the examination system adopted by the Institution of Civil Engineers, and then attacked the question of specialisation:—

Under modern conditions the strongest bond of a union between all branches of engineering will be found on the scientific side. Specialisation in individual practice has already gone far and is likely to extend; but the scientific basis of engineering will always have much that is common to all departments. . . Most men are content to choose a line and to endeavour to win distinction therein. It is a good thing, under these circumstances, that there should still remain some ground of common interest, such as science provides. Specialisation in engineering practice is inevitable. It should never be permitted to degenerate into isolation. Divergent as the branches of modern engineering undoubtedly are, they remain closely related. Many of them cannot have their lines of demarcation exactly defined. No branch has become so distinct that those engaged in its practice may not find it possible to benefit by taking an intelligent interest in what is being done in other departments. While no man can hope to keep himself fully informed on all sections of engineering, or to assimilate the enormous mass of current technical literature, he may advantageously study the general lines of advance, and will often find valuable, if unexpected, suggestions bearing on his own work. I desire to record my equally strong conviction that for the "average man" an early specialisation of practice is advantageous, and generally leads to greater success. Probably for many of the members of this institution there has been no alternative, and it has been necessary to undertake work in some department of engineering at an early period. Provided the preliminary education has been satisfactory there is not, in my judgment, any reason for regret if this necessity has arisen.

Sir William White devoted the remainder of his address to the subject of the education of engineers. He advises that a boy should commence his practical work in the shops directly he leaves school, "at a time when 'roughing it' becomes easy and observation is quick, while the facility of acquiring handicrafts and manual dexterity is greatest":—

During this period of practical training it is most desirable that scholastic knowledge should be maintained or extended. Unfortunately, this is often neglected and the loss is serious. In many cases arrangements can be made by which boys need not be subjected to such extreme physical exertion as would prevent evening study: and in all great industrial centres suitable evening classes are now established in which instruction can be obtained. If this programme is carried out a young man finishes his practical course without loss of educational knowledge; and if he has the means and the capacity, he is well prepared for entry into a technical college, at an age which permits him to obtain the full benefit of theoretical training and laboratory work. . . . Perhaps the ideal system of training is that which permits an engineering pupil to continue his scholastic training side by side with the preliminary practical experience, as the medical student attached to a hospital does. . . . The system of training adapted by the Admiralty for its staff of constructors and naval engineers approximates to this ideal.

In conclusion we quote the following suggestions of a course which might well be followed by more colleges and engineering firms than it is at present:—

It must be admitted that in many directions a department of the State can do what is impossible to private enterprise . . . Still, Admiralty experience shows the advantages of that concurrent study, and it is a matter worth consideration whether something of the same kind might not be done for students in technical colleges, most of which are situated in great industrial centres. Subject to suitable regulations and limits, providing against injury or embarrassment to the business of private firms, it would not seem impossible to provide facilities by which at least senior students should keep closer touch with the practical side of their future work. Cases have come under my own observation where such facilities have been granted by important firms with excellent results.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, October 28th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda:—(1) "An Influence Machine," by W. R. Pidgeon; (2) "The Repetition of an Experiment on the Magneto-optic Phenomenon discovered by Righi," by Prof. Silvanus P. Thompson, F.R.S.; (3) "The Magnetic Fluxes in Meters and other Electrical Instruments," by Albert Campbell.

TUESDAY, November 1st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. First Ordinary Meeting, when Mr. W. H. Preece, the President, will deliver an Address, after which the Medals and Prizes awarded by the Council will be presented.

THURSDAY, November 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

4 p.m. Special General Meeting for Members only, at 28, Victoria-street, S.W., to consider the proposed revision of the Articles of Association.

Digitized by Google

THE THOMPSON-WALKER SYSTEM OF ELECTRIC TRACTION.

Quite the latest development in electric traction is the surface-contact system jointly invented by Prof. Silvanus P. Thompson and Mr. Miles Walker. During the past week we have been afforded opportunities of examining the details of construction and working of this system on a short length of tramway which has been laid down near Willesden. A technical description of the Thompson-Walker system appeared in our issue of September 30th last (*The Electrician*, Vol. XLI., p. 751), in a reprint of a Paper communicated by the inventors to the British Association. It will be unnecessary to repeat the details of that description now, but it may assist the reader to understand the system if we give some account of what we saw at Willesden.

Car and Portion of Track near Willesden, equipped on the Thompson-Walker Surface-contact System of Electric Traction.

It must be borne in mind that the main objects of a surface-contact system of electric traction are to obviate, on the one hand, overhead construction in the form of poles and trolley wires and trolley masts on the cars, and, on the other hand, to dispense with slots or other cavities in the road surface. The ideal surface-contact system consists of an insulated series of conductors laid flush with the road surface, each individual conductor being made electrically alive only immediately when the car passes over it. In practice, the contact-pieces cannot be quite flush with the roadway surface, as it is necessary that they should come into contact with a sliding bar or skate carried beneath the car; they must, therefore, project a little above the surface. In practice also hitherto it has been very difficult and almost impossible to guarantee that the contact-pieces shall be rendered inert or non-electrified after the car has passed. The dangers attendant upon live plugs occurring at random upon the road is so great that the Board of Trade would not sanction any system in which there was the remotest possibility of such an event occurring, It is claimed for the Thompson-Walker system that although "it will, of course, be said that in every traction system there must be *some* risk; in this system that risk is upon the happening of something which is inconceivable." While we think this is putting it rather strongly, we nevertheless concede that the mechanism below the contact road plug is much less liable to get out of order, in a way that would keep the plug live after the car had passed in any other surface-contact system we have as yet seen. In order to throw one of these plugs into electrical connection with the mains, it is absolutely essential that a live piece of iron or other highly magnetic substance at a pressure of something like 500 volts should be immediately over and in contact with the plug. Other systems have depended upon the proximity of either a piece of iron or of an electrified conductor; but in the Thompson-Walker system the conductor must be both electrified and be composed of iron. Thus the chance of any ordinary vehicle enlivening a knob is reduced to a very small minimum—practically, indeed, to an impossibility.

One of the defects which has to be guarded against in a surface-contact system is the maintenance of electrical contact between the plug and the feeder by leakage. In the Thompson-Walker system all parts, which are either live or which become live when the car is passing over the stud, are so surrounded by permanently-earthed metal that any leakage must escape to the earth and cannot raise the electrical pressure of the knob. So that, even should leakage occur, the knobs are not rendered dangerous. If, therefore, from leakage, or from any other cause, an excessive current passes a fuse within the plug box is blown and the plug is isolated.

The mechanism within the plug box is completely enveloped in paraffin oil, and is thus prevented from sticking either through rust or the accumulation of dirt. The contacts are made by means of mercury cups shunted by carbon breaks. The main current is never broken at the mercury cups, but these are opened first and immediately afterwards the carbon breaks open the circuit. Thus no flashing occurs at the mercury surface.

The experimental line which has been laid down near Willesden consists of a short length of single track, with a turn-out at one end and a sharp grade curve at the other end. The car is an ordinary double-decked car, capable of carrying as many as 60 persons, and when operated fully loaded ran smoothly and satisfactorily over the line in either direction. There is provided on the car a small 500-volt accumulator connected with an additional plug on the controller, by means of which the skate can be made live to the required pressure in the event of the car passing over a dead plug, and thus losing electrical pressure from the mains. The operation of throwing the skate on to the battery can be performed so quickly as to make no noticeable change in the speed of the car. When, through breaking a fuse or from any other cause, it is necessary to replace the mechanism below the plug, it is simply necessary to undo three screws on the surface and lift out the plug and the mechanical gear below it, the whole coming out bodily. We timed this operation, and found that it could be completely carried out in 37sec., while a plug could be removed and a new one put in in about 1min.

One of the objections commonly raised against all traction systems that rival the overhead trolley is the very much greater cost of these rival systems. From figures supplied to us in a pamphlet which has been circulated, we learn that the relative costs of the Thompson-Walker surface-contact system, the overhead trolley system, and the open conduit system are as follows:—

COST PER MILE OF SINGLE TRACK.

I.—*Overhead Wire System.*

Trolley wire and adjuncts	£300
Poles	400 to 1,200
Permanent way and paving	3,500
Feeders	4,000
	£8,200 to 9,000

Digitized by Google

II.—*Open Conduit System.*

Cost of conduit under favourable conditions, including conductor rails, insulators and drainage	£3,900
Permanent way and paving	3,500
Feeders	4,000
	£11,400

III.—*Surface Contact System.*

180 to 360 boxes costing, say, £5 apiece	£900 to 1,800
Permanent way and paving	3,500
Feeders and adjuncts	4,200
	£8,600 to 9,500

From these figures it will be seen that it is claimed that the new system is but slightly more expensive than the overhead equipment. As, however, the new system has never been made the subject of actual practical contracting work, it still remains to be seen whether it can be put in profitably at the price stated.

In conclusion, we may observe that since the Thompson-Walker system is operated at the same pressure as the ordinary overhead trolley, viz., 500 volts, it can easily be combined with the latter. In other words, cars might be equipped to work on the Thompson-Walker system in narrow streets where overhead equipment might be prohibited, and to run on the overhead trolley system in suburban and outlying districts where the overhead equipment would be permissible. Indeed, it seems to us that in the event of the new system proving suitable for ordinary commercial tramway work this will be found to be its most useful feature.

PROGRESS OF GLASGOW CORPORATION ELECTRICITY WORKS.

Any one who has recently had occasion to be much about the streets of Glasgow cannot fail to have noticed the large extensions that are being carried out in connection with the electric lighting of the city, even if they are not interested in the subject itself. When the matter is looked into more carefully these extensions appear all the more startling. It is, of course, admitted on all sides that the lighting of Glasgow, and the general electrical arrangements were very much behind hand, and when Mr. Chamen was appointed less than a year ago he had a very serious position to face. The present station is now as full of plant as it can possibly be, and only holds some 3,000 to 4,000 H.P. even at that, and last winter even with the assistance rendered it with the two large batteries of accumulators that were put down whenever there was a little extra tax on it due to fog, &c., the voltage would fall to, from the consumers' point of view, an almost negligible quantity. Seeing that consumers have been added in considerable numbers since, it will be seen that it was imperative that further plant should be got ready to prevent serious consequences as far as a continuance of the supply was concerned.

Within a very short time of his appointment Mr. Chamen has formulated his general scheme for the lighting of the city, and obtained the approval of the Corporation to it. Generally speaking, this scheme consisted in laying down two stations, one on the north side of the river Clyde for a possible output of 30,000 H.P., and one on the south side of the river for a possible output of 20,000 H.P. It was, of course, impossible to have these stations in any way ready for this winter's load; it was, therefore, decided to advertise for plant, amounting to a total of 2,000 to 3,000 H.P. in any sized units, the only stipulation being the question of delivery; and there was offered and accepted for delivery this autumn a large marine engine coupled to a German dynamo, an American engine coupled to two American dynamos, and two small English high-speed sets. Foundations have been put down for these plants in the new engine house on the north side at Port Dundas, and a temporary shed erected over them, steam being supplied by a couple of Babcock boilers, which are fitted to form part of the permanent battery. This work is well forward now, and as it will not be long after these lines are in print that the plant will be ready for taking up part of the load of the city, and so relieving the present station, a few words will not be amiss as to the general arrangements of the station. The ground secured for the station on the north side is adjoining the Forth and Clyde Canal, which is the property of the Caledonian Railway; the configuration of the ground is such that the level of the canal is the same as the coal store which is over the boiler room, thus the coal can be delivered directly either from the barges or railway trucks right into the hoppers to feed the automatic stokers if required. The boilers are arranged in one long line running parallel with the canal bank, and alongside this runs the engine room. The building is made up of three sections; in the centre what may be termed the main portion, consisting of one-third of each of the boiler room and engine room, with in front a central block running up into a tower, containing the engineer's office, &c., and on either side of this the battery rooms; it is this portion that is now being pushed on with; the other two portions consist simply of extensions of the boiler and engine rooms in either direction. This arrangement even in its incomplete form makes a very compact and handsome building, but when completed it will probably rank as the finest electric light station in the kingdom.

So much for the station buildings; now as to the mains and cables. The system of distribution is, of course, a three-wire system, but it is, we believe, the first town to take the full advantage of the Board of Trade permission, and lay down a supply of 250 volts or 500 volts across the outers. The first step was made some little time ago, when a large part of the town was changed over from the 100 volt supply to the 200, but as soon as the new plant is at work a large section will be further increased to 250 volts, and as the new station gradually takes up the load the present station will be shut down. The distribution may be termed a purely feeder distribution, the network being of comparatively small section, but being very liberally supplied with feeders; at present there are some 20-30 triple concentric feeders being laid from the new station to various points on the north side, one of them being carried across the river to form a junction with the south side station. These feeders are all of 1in. × 1in. × 4in. section. The contract for them was divided between the British Insulated Wire Co., of Prescot, and Messrs. Callender, of Erith. Both feeders and network are plain lead covered, and are being laid in heavy earthenware troughing, and filled in solid with bitumen. This will make a very sound and permanent piece of work.

TELEGRAPHS AND TELEPHONES IN PERSIA.*

The first telegraph line in Persia was established about 36 years ago, and in the beginning was vigorously denounced and opposed by the priests as being a species of magic, and closely allied to other evil principles greatly subversive of religion and the best interests of the State, and as such not to be permitted to have a place in the economy of Government. This opposition, however, was overcome, and the class which resisted so stoutly at the first now use the telegraph with the greatest indifference. In the year 1862 the construction of a telegraph line from India to England through Persia, Russia, and Germany was commenced, and it began working on January 1, 1870. Some work had, however, been carried on for three or four years by a line through the Euphrates valley; but according to the United States Vice-Consul at Teheran, this was not by any means of a satisfactory character, and serious errors, delays, and interruptions occurred. The line is still used occasionally. The Indo-European is a well-constructed and efficiently-managed line. From Bushire to Karachi there is both a cable and a land line. This line provides the local native administration with one wire which can always be depended upon. The local lines, with the exception of the one wire mentioned above, are the property of the Persian Government. The ownership was acquired by the cost of construction, and has been maintained by defraying the expenses of preservation. The actual administration is deputed to one man, who, until very recently, contributed to the Government, £2,400 a year. This royalty has now been raised to £6,000 a year. The yearly receipts of the telegraphs have been about £12,000, and the expenditure equals, if not exceeds, the income. In consequence, certain reforms are to be initiated in the direction of compulsory payments. It is stated that fully 50 per cent. of the telegrams are sent free. Officials of the Government

Digitized by Google

(central and local), priests, expounders of the law, relatives of persons connected with the working and the administration, and everyone who can provide himself with a reason or excuse, send their telegrams free of expense. As this system has been growing for many years past, and most of those who have benefited by it are in a position to give trouble, the management find it difficult to introduce changes necessary for their own protection. The Persian local system comprises about 3,100 miles of wire and 86 offices for the receipt and despatch of messages. The wire provided by the Indo-European administrations, gratis, is about 1,300 miles long, and extends from the Persian Gulf to the Russian frontier. Stamps are not used for any purposes in Persia, except for letters. Messages are restricted to 10 words, at a charge of 2½ krans (about 9d.). The actual charge for the message is 2 krans, and the half kran is for the paper on which it is written. In case the message extends to a large number of words it is calculated at the rate of 10 words to the two krans, and not 2½ krans. This tariff is the same for any distance in Persia; there is only one charge. The Persian newspapers rarely contain information of sufficient importance to be sent by telegraph, consequently there is no Press rate, and, indeed, there are very few Press messages. There are four newspapers in Persia printed in the vernacular, and under Government control. These should be issued once a fortnight, but they are often issued at longer intervals; they are in no sense considered as leaders or exponents of the ideas or feelings of the people. As regards telephones, the late Nasredin Shah on December 8, 1889, granted to the then Minister for Foreign Affairs a concession for electric lighting, the introduction of telephones, phonographs, and the application of electricity to industrial purposes to the whole of Persia, with protection to the monopoly for the period of 60 years. This concession was transferred to an American citizen for a certain valuable consideration, but for want of means the purposes of the concession have not been put into execution. In order to protect the concession from lapsing, two or three wires were put up and kept in a workable state, and are now in use. Five years ago the railway and tramway company commenced erecting private wires for anyone who would undertake the expense, and they established an exchange office on their own premises at Teheran. It has not been extended to any other town. So far, no records have been kept of the number of miles of wire erected, but the Vice-Consul says that from his observation he should estimate it at about fifty miles—this is including the wires into villages of summer resort, and those to different parts of the city. At the present time there are 15 owners of private wires, each of whom pays the company about 8s. 6d. per month for keeping the wires in repair, and the instruments in order. The receipts about balance the expenditure, but this only includes the free use of the lines by the Company, who provide the only office there is in the city, and two in the country during the summer months. As messages are not received from the public, no tariff has been formulated. Subscribers are put into communication, and use the telephones as long as they wish. As a more extended use of the telephone would interfere with the receipts of the telegraphs, permission to use it has not been granted to distances appropriated by the telegraphs.

ELECTRICITY WORKS ACCOUNTS.

Nottingham Municipal Electric Supply Works.

The electrical undertaking of the Nottingham Corporation, the accounts of which form the subject of our first table this week, was started in September, 1894; it has, therefore, completed its third year of working, and, moreover, in a manner which indicates very satisfactory progress, both as regards output and economy of working.

The borrowed capital amounts to £77,865, raised at rates varying from 3 per cent. to 2⅝ per cent., while the expended capital has reached £75,996, representing £79 per kilowatt capacity of generating plant. An increase in the number of consumers from 334 to 480 during the year has resulted in an increased equivalent lamp connection of 48 per cent., or from 25,725 to 38,140. The corresponding increase in the output in units sold is 61·6 per cent. on 297,185, bringing it up to 480,881 for the year ended March 31st last. A substantial diminution of the costs of 1896-7 has been effected, lowering them to 1·83d. per unit—a value which has not been beaten by any station we have yet analysed of the same or lower output. Both works costs and management and property charges, but especially the latter, have conduced to the total reduction effected.

A working profit of no less than £7,067 has been made, the total costs bearing the low ratio of 34 per cent. to the revenue, £8,503 has been carried to the depreciation fund, £1,897 to the sinking fund and towards repayment of loans, and £2,168 paid as interest on loans.

As giving some indication of the progress of the concern, it may be stated that for the year 1895-6 the number of units sold was 171,654, of which 11,564 were for public lighting. The revenue was £6,638, and the expenditure £2,090, with an equivalent number of lamps connected of 17,400.

The National Electric Supply Company (Preston).

This Company commenced the supply of electricity in Preston in August, 1892; therefore, the last accounts analysed in the table are those of the fifth year of working. Of the total capital received, viz., £66,794, £39,694 is by shares and £27,100 has been borrowed on Four and a-Half per Cent. Debentures. The total amount expended as capital is £70,201, being at the rate of £117 per kilowatt of generating capacity.

The number of consumers have been increased by 50 during the year and the (8 c.p.) equivalent lamp connection by 27 per cent. or to 23,300, as compared with 18,300 in 1896. A large proportion of this increase in the connections to the mains occurred towards the end of the year, so that the improvement due to the extended custom was not to be expected in the accounts for 1897. The output for the year has reached 371,301 units sold—an increase nearly 16 per cent. A total revenue of £7,829 was received showing an average price per unit of 5·06d. We regret to notice that the total costs per unit have risen by nearly 0·4d. This is due, however, chiefly to the management charges; salaries having risen by nearly 0·3d., and one or two abnormal special charges which have been included under management causing a further increase. The works costs have fallen perceptibly. A working profit of £4,118, together with £500 previous balance, allows of £700 being paid in respect of depreciation, £1,188 as interest on loans, and a dividend of 5s. per share being paid on the ordinary shares which absorbs £2,713, leaving £18 balance carried forward. A small alternating plant has been added to the machinery to supply current to the outlying districts.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

SPECIAL NOTICE.

Last week's number of "The Electrician" completed Volume XLI. With this week's number is issued (Gratis) the Index to the Volume.

Complaints of non-receipt should be promptly made to the Publisher.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

POLYPHASE TRACTION.

The question of electric traction is now so much to the fore in England, particularly in technical circles, that it is by no means surprising that polyphase working in this connection should attract very considerable attention. The polyphase system has already been tried to a certain extent for traction purposes on the Continent and in America; and, indeed, in one instance, namely the Dublin installation, in the United Kingdom. Nevertheless, the amount of experience gained has been so small that the relative advantage of the system as compared with the almost universal continuous-current overhead-trolley system is still a matter of keen debate. The question is still further complicated by the fact that there are two distinct polyphase systems in the field; and if the experience of polyphase traction as a whole has been very limited, the experience of each of the systems considered individually has been even more limited still. The first of the two systems is what may be called the combined polyphase and continuous-current system, and the second the polyphase-motor system. In the former the power is transmitted from the generating station to various sub-stations by means of high-potential polyphase currents, which in the sub-stations are transformed by means of rotary transformers to continuous currents of 400 to 500 volts' pressure, and with these the car-motors are supplied in the ordinary way by means of trolley wires. In the latter system the power is, as before, transmitted to sub-stations by means of high-potential polyphase currents; but in the sub-stations, in place of the rotary transformers, stationary transformers are employed which merely reduce the potential to a safe value, the current remaining polyphase and the car-motors being, consequently, also polyphase. In discussing the relative merits of the three competing systems—the ordinary continuous current, the combined polyphase-continuous-current and the polyphase-motor—the first and perhaps most important question that arises is, How do they severally stand as regards interference with telephones, telegraphs and observatories, and as regards electrolytic action upon neighbouring pipes and metal work? Accurately speaking, however, this is not a

Digitized by Google

single question, but rather three separate ones, for the magnetic disturbance due to the outgoing and return metallic circuits is quite distinct from the disturbance due to currents leaking from the return circuit through the earth; and, in turn, these magnetic effects are quite distinct from the electrolytic effects of the earth currents. As regards the first of these, the polyphase-motor system seems to be at a great disadvantage as compared with either of its rivals, which are of equal merit in this respect providing that in both cases concentric feeders are employed; the magnetic effect of a concentric cable carrying equal currents in opposite directions being, of course, nil. In both systems the disturbance due to the currents in the trolley wire and in the rail return are similar, since in both cases similar continuous currents are supplied to the motors on the cars. But when polyphase motors are employed, though the feeders may be concentric, the currents to and from the motors must be carried by two trolley-wires and by the rails, and since these currents are alternating the disturbance they create is much greater than in the case of the continuous currents of the direct-current or combined systems. In confirmation of this we find that at Lugano, where polyphase motors are employed, the telephone system has been thrown into the greatest confusion; while on the new Jungfrau railway, though the telephone wires which, are carried on the same poles as the three-phase current circuit, are crossed every 550 yards, the disturbance is still too great for the satisfactory transit of messages. Further, should it be decided to use an insulated return, as may very well happen in this country where a drop of only seven volts is allowed, or an uninsulated return, and where vested interests in telephones, pipes, &c., are so carefully protected, the continuous current system might possibly be worked with double trolley wires; whereas the three-phase motor system, which, even employing the rails as one of the circuits, and using the double trolley, would find that the complexity introduced by a third trolley-wire made satisfactory working almost impracticable. Two trolleys are a sufficiently exasperating condition; three would be prohibititive. As regards the effects upon telephones, &c., of leakage currents through the earth from an uninsulated return, the polyphase-motor system would again be at a great disadvantage; for the earth currents would be alternating, and consequently their magnetic effects, at least, would be much greater than with continuous currents. With respect, however, to the third source of trouble, the electrolytic action of the leakage currents, the polyphase-motor system would undoubtedly be superior to the others, since the electrolysis set up by alternating currents seems to be practically negligible as compared with that due to continuous currents. It is strange, by the way, that the question of alternate current electrolysis should have attracted so little attention from investigators; very little seems to be known about it. But it must be borne in mind that, should the other systems adopt the insulated return, electrolytic troubles would be entirely done away with, and these systems would be, if anything, better in this respect than the polyphase-motor arrangement which cannot adopt the overhead return on account of the complexity of circuits which would ensue.

But leaving the disturbance effects of the different systems, let us consider their relative values from the engineering, which is ultimately the economic, point of view. In the first place the polyphase motor has the advantage of requiring only collecting rings, and not a commutator, as is the case when direct currents are employed; and, beyond all doubt, this is an advantage, though, of course, not of such great importance as at once to give the polyphase system preference over the others. Again, the polyphase motor can be more compactly and mechanically constructed owing to the simplicity of its parts and their symmetrical arrangement, and a leading Continental manufacturer informs us that it is a matter of practical experience that for the same speed and output it can be made lighter than the continuous-current motor. Finally, the polyphase system, as compared with the combined polyphase continuous-current system, has the advantage of requiring only stationary transformers in the sub-stations, thereby effecting a saving both in first cost and in the annual charge for attendance. This advantage, however, is not so great as it might at first sight seem to be, since the rotary transformer requires remarkably little attention; at Dublin, indeed, it has been found possible to leave the sub-stations in the charge of boys. Again, though the polyphase motor may be lighter than the corresponding continuous-current machine, this does not necessarily imply that it is cheaper, for its magnets have to be laminated, and this adds greatly to the cost. Likewise in the matter of regulation the continuous-current motor has the advantage, since its speed and torque can be varied without appreciable loss of energy, by shunting more or less of the series field coils and by adopting the series-parallel system with two motors to each car; whereas with polyphase currents the general method of regulation, at least at present, is by the insertion of non-inductive resistance in the rotor circuit, which leads to the direct loss of energy in heat. But it should be remembered that Mr. C. E. L. Brown advocates regulation, at all events in part, by means of alteration of the stator circuits from the star to the mesh formation, and by cutting out a certain number of the poles and thereby altering the speed of synchronism. On the whole it is perhaps too early to say that the efficient regulation of the polyphase motor is impossible, even for ordinary tramway work in crowded thoroughfares where frequent stoppages and slow speeds are necessary; although at present there can be no question that the system is better suited for light, or indeed even heavy, railway work, where long runs at approximately full speed are the general rule, than for the varying conditions of the ordinary street tramway. But in so far as what has been called the power factor of the polyphase motor is always less than unity,—or, putting the same thing in other words in so far as the current in the trolley wires has to be greater than that corresponding to the power developed in the motor—owing to the lag between E.M.F. and current, and the area of the trolley wires has to be increased for the same percentage loss in the line—the polyphase motor system must be inferior to systems employing continuous currents.

To sum up, we may say that, on the whole, both from the point of view of inductive and earth-current disturbance and of economical and practical working, the advantage, at any rate at present, lies with the continuous-current motor. Of the two continuous-current motor systems, however, the combined polyphase-continuous-current will in general be the most economical to adopt—that is to say, that whenever the feeders are necessarily of considerable length, owing to the length of rail to be worked, or to the desirability of having the generating station in a locality where land is cheap, or where there are exceptional facilities for procuring fuel and water, or where water power is available, it will be found that the saving in the capital expended on copper in the feeders, owing to the use of a high potential, more than compensates for the extra cost of the rotary transformer sub-stations, and the small annual charge for maintaining them: though, of course, each particular case must be considered on its own particular merits.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Luminescence Lamps.—The alleged economy of luminescent or fluorescent sources of light is based upon the fact that the maximum energy radiated by them lies in the visible spectrum, and that the infra-red heat rays are practically absent. But before jumping to the conclusion that the luminescence lamp is the "light of the future" it is necessary to determine by what expenditure of energy its pure light can be produced. Balmain's luminous paint reproduces about 5 per cent. and a fluorescein solution about 1 per cent. of the incident light. E. Wiedemann has determined both the heating and the lighting up of a luminiscent screen by the impact of cathode rays, by introducing into the vacuum tube a thinner tube with a bulb containing water, and painted with Balmain's paint or other luminescent material. The calorimeter tube was open to the air and contained a thermometer for observing the heating effect of cathode rays impinging upon the luminous paint. At the same time, the luminous energy was photometrically determined by comparison with an amyl-acetate lamp. It was found that the heating accompanying a brightness of one Hefner candle was about 1 gr. cal. per second. This means that only about 5 or 7 per cent. of the incident energy is converted into light. In a Puluj lamp, painted with Sidot's blende, the heating per candle-power was three watts, that being very nearly the same ratio as in incandescent lamps, and the same efficiency as in photoluminescent substances.

[Wiedemann, *Wied. Ann.*, No. 9, 1898.]

Vacuum Tubes v. *Coherers.*—A. Righi appears at last to have invented a vacuum tube which is capable of seriously rivalling the coherer as an electric wave indicator. The details of its construction are not given, the reason being that they are "too complex," but the tube has the peculiarity of showing a continuous streak of light between the two electrodes, which breaks up under the influence of electric waves into the accustomed succession of positive strata, dark space, and cathode light. The cathode is a wire, and the anode a disc, and under ordinary circumstances a cone of light extends from one to the other. This condition is resumed after the electric radiation has ceased. The curious thing is that the effect is produced also when the radiation impinges upon some portion of the circuit of the vacuum tube not too far away from the tube. Hence it is probable that the influence of the radiation does not affect the gas in the tube, but only the electrodes. But besides the optical phenomenon, which is in itself a valuable indicator of the presence of electric waves, there is a change of resistance, as in the coherer, which is indicated by a galvanometer. Often, the current is increased to three times its original strength when the tube lights up, and that effect might, of course, be multiplied indefinitely by suitable relays. The advantage of not requiring a special mechanism for restoring the original resistance is obvious, but, on the other hand, Righi does not seem to have experimented with transmissions longer than seven yards.

[Righi, *Nuovo Cimento*, July, 1898.]

Currents Generated by Röntgen Rays.—In 1897 Perrin succeeded in obtaining differences of potential between two different metals when exposed to X rays, and even observed a small constant current of about 10^{-8} amperes on joining them by a wire. A. Winkelmann has made further observations on this interesting subject. He placed a Röntgen apparatus in a leaden box with an aluminium window. In front of the window he mounted an aluminium plate, and behind that a copper plate. On working the apparatus and connecting the two through a galvanometer, a small current was indicated, which was increased by reducing the distance between the plates. A battery of plates could be constructed by mounting plates of the two metals alternately one behind the other, taking care, however, that the insulator between them was not, like mica, for instance, impervious to X-rays. The resistance of one such battery was found to be 180 million ohms, and to increase as the battery was moved away from the Röntgen apparatus, evidently owing to the lesser degree of ionisation of the more distant air. Further, the resistance of the layer of ionised air diminished as the thickness of the layer was diminished, down to a certain minimum. At very small thicknesses the recombination of the ions is so rapid that the current intensity is thereby diminished. The author calculates the proportion of ionised molecules of air in the total number of molecules at $4{\cdot}6 \times 10^{-12}$ at least, in a position of maximum conductivity.

[Winkelmann, *Wied. Ann.*, No. 9, 1898.]

Magnetic Hysteresis. — F. Niethammer examines the behaviour of sheet iron when put through a magnetic cycle, not step-by-step as in the older experiments, but in rapid succession, by means of alternating currents. He finds that Steinmetz's formula $A_v = \eta B^{1\cdot6}$, expressing the relation between the hysteresis work and the induction, only holds within narrow limits and even there only approximately. The coefficient η is different for different kinds of magnetisation, such as the magnetostatic, the alternate current, and the rotating-field method. The curves of magnetisation and permeability are much lower for alternate-current than for static magnetisation, and they are the lower the greater the rate of alternation. Hence it is possible to impart a stronger magnetisation by means of a steady field than by means of a varying one. On the other hand, the hysteresis work is greater when using an alternate current. It does not matter whether the curves of the latter are flat or sinusoidal, but the hysteresis work is much diminished in the case of pointed curves, when the maximum induction is the same in both cases. When a body is made to rotate in a magnetic field, the work of magnetisation per cycle increases up to a certain high induction close to saturation, and then decreases. At B = 14,000, the rotatory hysteresis is sometimes double the linear hysteresis. But for higher values, the rotatory hysteresis gradually becomes the smaller of the two.

[Niethammer, *Wied. Ann.*, No. 9, 1898.]

Corpuscular Theory of Röntgen Rays.—The most popular theory of cathode rays at the present moment is a corpuscular one, while the most popular theory of Röntgen rays is the undulatory or "hedge-firing" theory elaborated by J. J. Thomson and Johnstone Stoney. The Dutch physicists, Vosmaer and Ortt, recently proposed a tentative corpuscular theory of the Röntgen rays, which, however, was somewhat roughly handled on its appearance. Before seeing their Paper B. Walter worked out a theory on very similar lines, which has a large number of considerations to recommend it, so much so, indeed, that its truth appears obvious and palpable at first sight. It consists in supposing that Röntgen rays are discharged cathode particles. It follows at once that they are not deflected by a magnet. After impinging upon the anti-cathode or other body and discharging themselves, the corpuscles are reflected in a diffuse manner and penetrate the walls of the tube. That they are able to do so is not surprising, considering that even the charged cathode particles are capable of penetrating a sheet of aluminium. Besides, since it is known that the ratio of the electric charge of a cathode particle to its mass is about 1,000 times that of the electrolytic charge of a hydrogen ion to its mass, it is evident that we have here to deal with particles much smaller than the electro-chemical ions. The only novelty lies in postulating the possibility of a divorce between the cathode particles and their charges. That Röntgen rays have a superior penetrating power is due to their electric neutrality. A copper bullet would have a greater chance of penetrating a forest of magnets than an iron bullet. The proportionality between absorption and the density of the absorbent is obvious. Ionisation of gases may be considered as a mechanical destruction of gaseous molecules by the impact of swift particles. When these particles are charged, like the cathode particles, the ionisation will be greater, as is indeed found to be the case. Porter's objection that the photographic activity of Röntgen rays is not affected by their transmission through a charged plate deserves consideration, but it is merely negative, and not in any way a crucial test.

LLANDUDNO MUNICIPAL ELECTRIC SUPPLY WORKS.

The motto "It is never too late to mend" appears to have been the guiding principle of the Llandudno District Council in the matter of providing a system of electrical supply. After having allowed the pier and several of the principal and largest hotels to be lit by independent, isolated electric light plants, and thus, having first cut away a considerable portion of the ground from under their own feet, the local authorities have carried to practical completion a scheme of public lighting and electricity supply, under the able direction of Mr. A. H. Preece, their consulting engineer.

After the extensive and important department of street lighting, there remains principally the work of supplying current for lighting the numerous hotels and boarding houses of that fashionable North Wales watering place, the business custom and motor loads being of quite subsidiary importance. This, of course, may be altered if a now projected scheme should be developed for supplying current to the electric railway which, in a short time, will run through Llandudno. But, at the present time, there seems considerable uncertainty as to whether the Company which will run this line will take current from the local authorities, through whose areas the line will pass, or will merely pay to those local authorities a certain annual sum for permission to generate their own current.

The electric supply works at Llandudno, although not yet officially opened, are practically in a position to run on a load and to supply the already considerable demand for current. The works are situated on a site adjoining the municipal gas works and some distance inland from the town. The accompanying map shows the position of these municipal works relatively to the town and system of mains. The electric supply station has been designed to work in conjunction with a refuse destructor plant, although it is not intended that the generation of steam shall depend entirely upon refuse destruction. There are three Babcock-Wilcox boilers, two of which are fired from Messrs. Beaman and Deas' destructors, the third being arranged only for hand firing; but all three boilers can be fired with coal or coke by hand if required. The location of the station close to the gas works enables coke fuel to be obtained cheaply and conveniently to both the electric light and gas departments, thus reducing the costs of these municipal undertakings.

The Beamen and Deas' refuse destructor is one of the most modern and generally used form of destructor, and has already been erected at numerous works throughout the United Kingdom. The general arrangement of the destructor relatively to the boiler plant is shown in the accompanying longitudinal section of the works. The refuse is carted up an incline to the tipping platform, and tipped direct into the mouth of a hopper about 18in. square, from which it falls down to a firebrick hearth carried on T irons, the hearth being set at an inclination of 52deg. Falling from this the refuse rests upon a fire grate of about 5 sq. ft. area, the firebars of which are of the ordinary stationary type with spaces of about $\frac{3}{32}$in., allowing fine ash to pass through. The gases pass over a firebrick bridge into a combustion chamber whence they pass through a short flue to the front lowermost flue of the Babcock boiler, and then take the usual course through the tube stack to the main flue leading to the economiser. We may add that a full description and account of the working of the Beaman and Deas' destructor is to be found in a recently published work, entitled "The Removal and Disposal of Town Refuse," by Mr. W. H. Maxwell. The Babcock-Wilcox boilers each have 1,741 sq. ft. of heating surface, and 86½ sq. ft. of grate area. Each is constructed in seven sections, each section containing seven tubes 16ft. in length; and there are two steam and water drums 36in. in diameter in each boiler. The boilers work at 150lb. pressure, and are

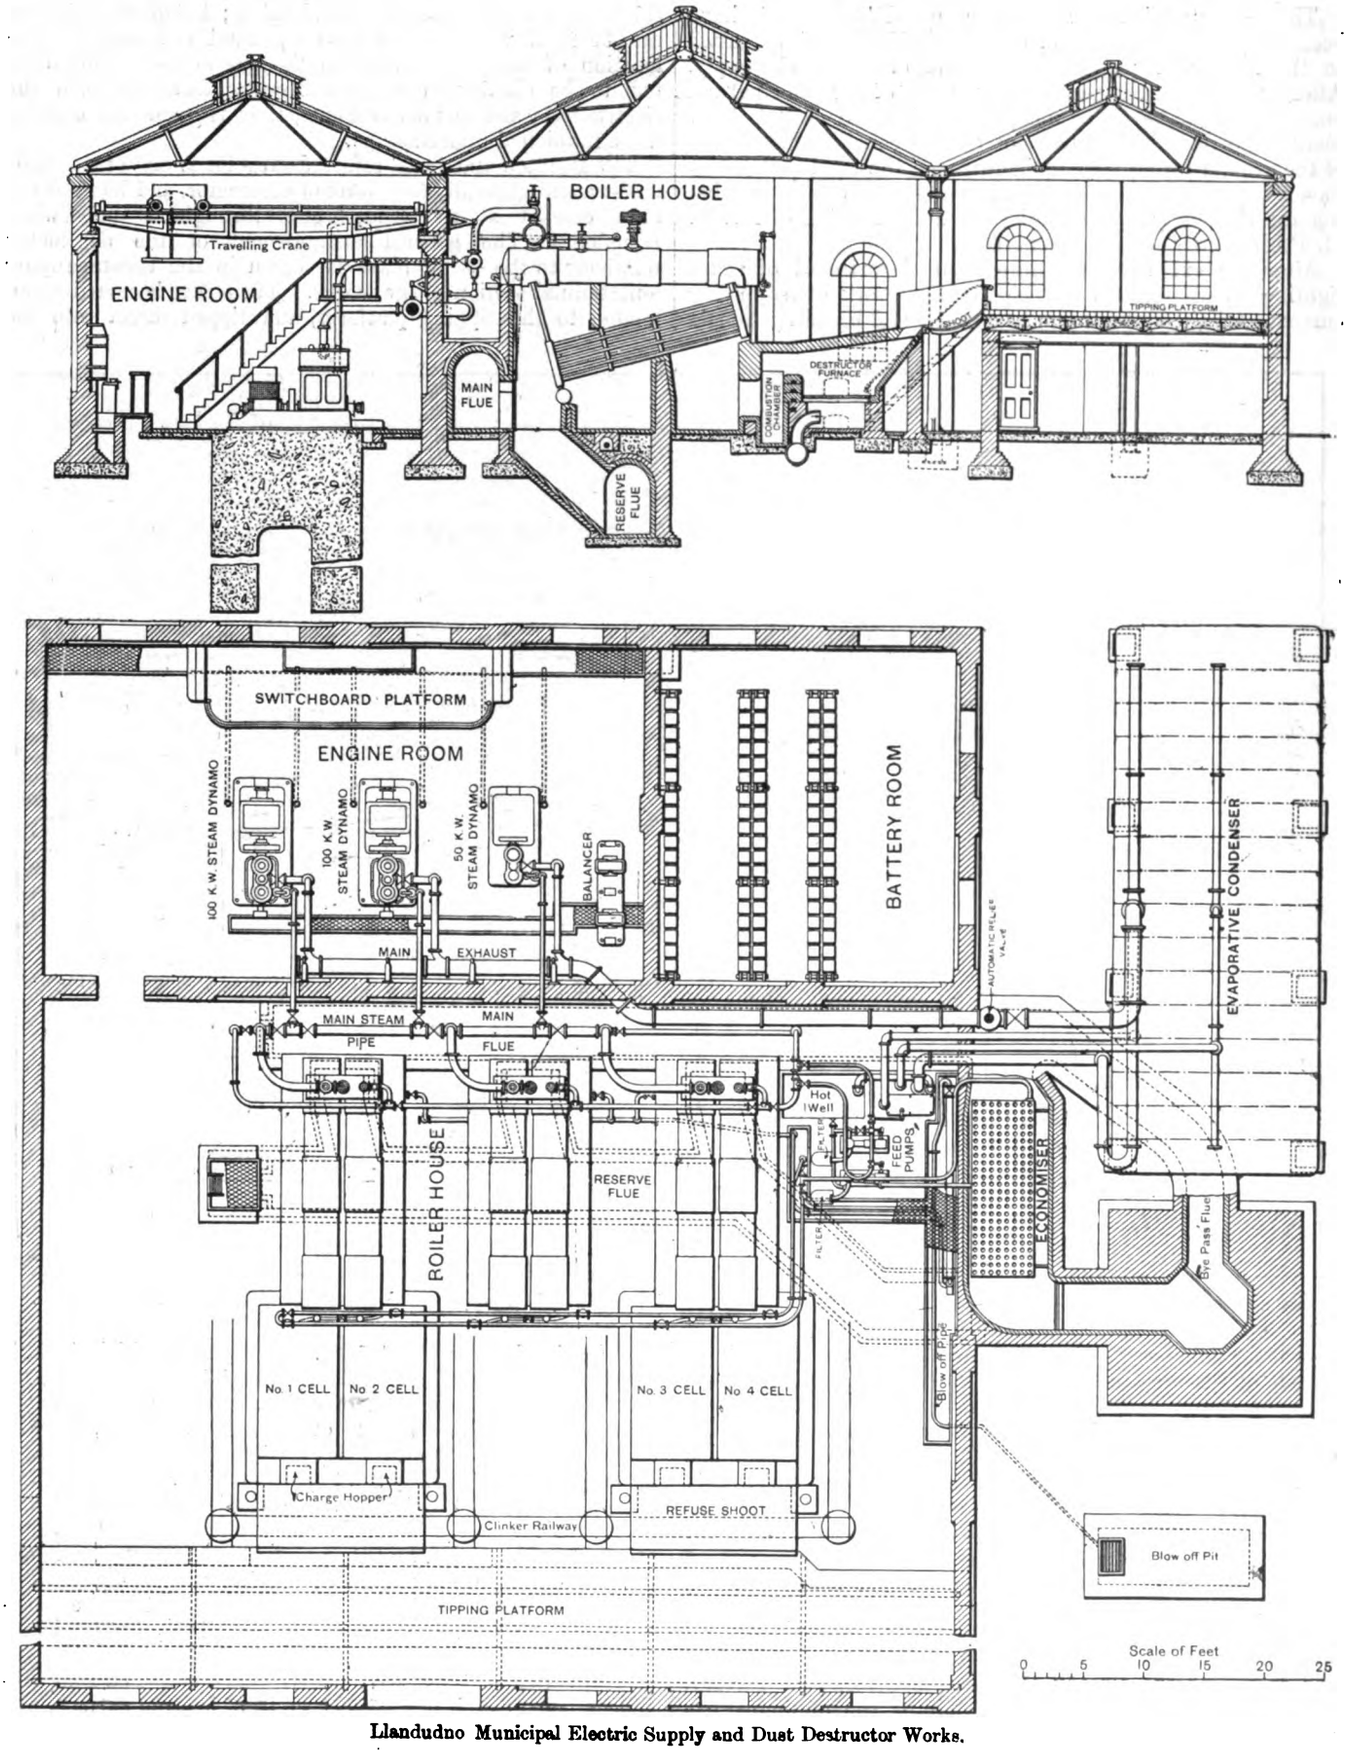
Digitized by Google

each capable of evaporating 5,000lb. of water per hour. In conjunction with the boiler plant there is a furnace economiser by Messrs. E. Green and Son, consisting of 192 pipes arranged in one group, fitted with deflectors at the back. Adjoining the economiser in the boiler house is a small recess used as a pump room, which is equipped with steam feed pumps by the Blake-Knowles Steam Pump Works, of the type described in our issue last week in connection with the Belfast municipal electric supply works, where they are also used. Immediately outside the boiler room a Ledward evaporative condenser is being erected. This, when completed, will be capable of condensing 7,500lb. of steam per hour. The condenser is of the usual tubular type, and is erected over a large cast-iron tank, having a capacity of 4,000 gallons. The air and circulating



Llandudno Municipal Electric Supply and Dust Destructor Works.

Digitized by Google

pumps for the condensing plant are driven direct by a vertical compound engine, this portion of the plant having been built and erected by the Sunderland Forge Co.

The engine room may be entered from the boiler room, and is on the same level. It is at present equipped with two 100-kilowatt steam dynamos and one 50 kilowatt steam dynamo, together with a motor generator for regulation and for charging the batteries. The generating sets were supplied under the contract of the India-Rubber, Gutta-Percha and Tele-

graph Works (Limited), and comprises two Belliss compound two-crank self-lubricating engines of their E. C. 7 standard pattern, each direct-coupled to a "Silvertown" S. D. 220 single horseshoe undertype dynamo with drum-bar armature, each set giving an output of 100 kilowatt at 440 to 500 volts when running at a speed of 450 revolutions per minute, and supplied with steam at 140lb. pressure, the engines being arranged to exhaust either into a condenser or to the atmosphere. There is also a third generating set composed of a Belliss E. C. 4-type engine coupled to a "Silvertown" single horseshoe undertype dynamo with Gramme-wound armature, and capable of giving an output of 50 kilowatt at 600 volts when running at a speed of 550 revolutions per minute. A balancer is provided consisting of two machines mounted on the same bedplate and coupled together, each armature being capable of carrying a current of 100 amperes and working at a voltage varying between 220 and 256 volts, so that it can transfer 25 kilowatt from one side of the three-wire system to the other. These machines are also single horseshoe undertype machines with drum-bar armature, and run at 1,000 revolutions per minute. A small motor has also been fitted for driving the scraper gear of the Green's economiser. Traversing the engine room, there is a small 25ft. span hand-traveller capable of lifting 5 tons, with a vertical lift of 18ft. This traveller was erected by the Sunderland Forge Co.

The switchboard in the engine room is very conveniently erected on a low platform facing the engine sets. It was constructed and equipped by Mr. James White, of Glasgow, and is built on a steel frame erected about 3ft. from the wall. It consists of 14 polished white marble panels screwed to the framework. The left panels serve as a dynamo section, the middle the balancing section, and the right panels a feeder section. The spaces between the panels are filled in with polished teak wood moulding, and surmounting the board is an ornamental frame carrying a self-winding clock, also the feeder and dynamo voltmeters. The back of the switchboard is enclosed, being reached through panel teak wood doors at the sides. Each dynamo panel is fitted with a Kelvin sector pattern ampere gauge, a maximum automatic cut-out and a double-pole change-over switch of the multiple contact knife pattern. Below each of the dynamo panels are the field regulators, the resistances in connection with which are fitted on the wall behind the board. At the top of the middle panel are fitted Kelvin recording voltmeters and two recording ammeters, while below these are the balancing ampere gauges and motor starting and field regulating switches. On the lower middle panel the voltmeter double-pole switches are fitted, while on each of the feeder panels there are mounted two Kelvin sector pattern ampere gauges, one on the positive and one on the negative section, the feeder fuses being mounted directly behind these.

The battery switchboard is mounted on a steel frame in a similar manner to the main board, and carries three polished marble panels. Two of these are provided with regulators for the 30 regulating cells of each of the two batteries, and on the top panel are mounted two Kelvin engine-room voltmeters connected between the middle of each of the "charge" bars of the battery. We may here say that the connections in the battery room from the regulating cells to the regulating board are of copper rod protected with anti-sulphuric enamel, the rods being carried on porcelain insulators fitted on wooden beams supported from the roof. A complete diagram of the switchboard connections for the main and battery switchboards is shown in one of the accompanying illustrations.

The battery room is reached from outside the building, and is a spacious apartment capable of holding considerably more cells than are at present erected. It now contains two batteries for the three-wire system, each battery consisting of 120 cells of 19 plates, in glass boxes, the output being 50 amperes for 10 hours, or 200 amperes for one hour. We may say that the batteries are of the usual type manufactured by Messrs. Pritchetts and Gold, by whom they were supplied for this station.

The feeders coming out from the station to the town are armoured triple concentric cables, manufactured by Messrs. W. T. Henley's Telegraph Works Co. (Limited). These are, of course, buried. The distributors are not triple concentric, but are of the three-core armoured pattern, and are also buried. They are insulated with impregnated fibrous material, lead covered and armoured with steel tape. A certain amount of earthenware conduit has been laid for future distributor extensions, but this at present is not in use. The arc cables consist of 7/16 single armoured cable, insulated with pure and vulcanised india-rubber, lead covered and protected by

Digitized by Google

an armouring of steel tape. All the cables were supplied by Messrs. W. T. Henley's Telegraph Works Co.

For the street arc lighting there are altogether 48 arc lamps, erected on cast-iron pillars. The lamps along the front, 30 in number, as well as those on important crossings, are fixed in carriers so arranged that the lamp itself is immediately over the centre of the pole, a canopy being provided to protect it from the weather, and to give a good appearance. The remaining 18 lamps are all fixed along the kerb at the side of the road, and are suspended from overhanging brackets. Three of the pillars are also fitted with double incandescent brackets. The lamps are run in groups from the distributor network, at 440 volts. Each group consists of eight lamps in series. Each of the six circuits is provided with main fuses and a main switch, the switches being so grouped that the total number can be turned on or off from three columns, two controlling switches being placed in each column. The lamps themselves are of the well-known Crompton-Pochin type. They are for single carbons, to burn for 18 hours without re-trimming, and are fitted with opalescent globes. These lamps are similar to those used in Edinburgh and many other important towns. Each lamp is provided with an automatic cut-out, which, in the event of the lamp "hanging-up" from any cause, immediately short-circuits it, so that the other lamps in that particular circuit will not be extinguished, nor will any damage be done to the lamp itself. In the base of each lamp post is fixed an "isolating" switch, which, in the event of any attendant having to do anything to the lamp, can be turned off, thereby entirely disconnecting the lamp from the circuit and bridging the lamp mains to enable the current to pass on to the next post. This arrangement enables a man to examine, or retrim with safety, any particular lamp without disturbing the others. Access to the carbon holders for trimming is obtained by lowering the globes. In the case of the bracket lamps the globes are merely dropped until their weight is taken by a pair of chains, but in the case of the central carrier lamps a rod is provided down which the globe slides. The current for the lamps is 10 amperes, and the height of the arc from the ground level is 20ft. The lamps on the sea front are fixed at distances of about 50 yards apart, but those in the town are a little farther apart, and are so arranged as to distribute the light to the best advantage.

In conclusion we desire to acknowledge our indebtedness to Mr. A. H. Preece, the consulting engineer, and to Mr. H. Morton, the resident engineer, for their valuable assistance in the preparation of this article, and to convey to them our warmest thanks.

A COMBINATION ABSORPTION AND TRANSMISSION DYNAMOMETER FOR LABORATORY PURPOSES.*

BY J. J. FLATHER.

In this Paper Prof. Flather described some recent improvements in his hydraulic transmission dynamometer, the most notable feature being the employment of a water-cooled pulley and a perforated rim which permits the use of a brake band that can be used for absorbing the power furnished to the machine. The fixed pulley which is ordinarily used to connect the dynamometer to the machine to be driven has internal flanges for carrying the cooling water, and the rim is furnished with a number of brass bushings drilled through endwise, and provided with a regulating screw, by which the amount of water admitted to the brake is readily controlled. The brake band is a three-ply cotton belt, 7in. wide, connected through two sets of tension springs to the brake-regulating screw. The brake band may be quickly removed, thus converting the machine into a regular transmission dynamometer. In either case an automatic record is obtained on a roll of paper which is caused to pass with uniform motion under an indicator pencil that records variations of pressure. In addition to the force curve traced by the indicator pencil the zero or datum line is traced by another pencil which is adjustable in position and may be located at pleasure on a line parallel with the axis of the shaft. Thus one is enabled to measure the total power required to run a given machine or any subdivided part of it. The two cylinders through which the driving power is transmitted are each 10 square inches in area and are provided with bronze pistons actuated by plunger pins, which may be located in either of two positions—the inner for ordinary work and the outer for extra heavy work, say, when it is required to measure 20 H.P., or when the speed of rotation is very slow. It will be understood that springs of varying degrees of intensity may be used to transmit the pressure from shaft to indicator pencil. These springs are changed, as in any ordinary indicator. The work of friction of the plunger in the cylinder is practically eliminated, since the combined area of the plungers is so much greater than in the indicator piston, and, as the indicator motion multiplies the distance moved by the indicator piston five times, it will be seen that the motion of the plungers is exceedingly small. The more recent machines are provided with adjustable casters, which permit the weight of the dynamometer to be carried by wheels or to rest firmly on the floor, as desired.

* Abstract of Paper read before Section D of the American Association for the Advancement of Science.

NEW DYNAMOS OF MESSRS. P. R. JACKSON AND CO.

It is now the aim of all dynamo makers to produce a machine which not only has the advantage of sparkless collection—a *sine qua non* nowadays—but also possesses the property of sparkless running at all loads without a change in the position of the brushes being necessary. After a series of experiments, lasting two years, Messrs. P. R. Jackson and Co. have now put on the market machines embodying these features, and even (it is claimed) able to stand considerable overload without an adjustment of the brushes being needed. All the machines are wound on the Sayers system.

Fig. 1 on the opposite page is an illustration of a 150-k.w. Belliss-Jackson steam set. The dynamo is 4-polar. The outer ring, or yoke, of the magnets is of Messrs. Jackson's own special steel, as are also the magnets and pole-pieces. The ring is partially enclosed at the sides with gun metal gratings, which not only afford protection to the field-magnet coils and the armature, but facilitate the work of connecting the magnet coils, and afford considerable support to the pole-pieces. The whole of the pole-pieces are cast and machined together by a special patented method of Messrs. Jacksons, which secures solid metal at the pole tips, and obviates the necessity of annealing the steel. The core is built on a spider, and the shafts are removable. We are also informed that the commutator is built on an entirely new principle. The bearings are of the separator type, and are self-oiling, without loose rings or other such devices. The brush holders are adjustable lengthways on the brush spindle, and there is also screw feed and hold-off adjustment. The springs, which are all of stout flat steel are enclosed in the body of the holder, and can be adjusted to give any desired brush pressure. The brush leads are attached underneath the commutator to two circular collectors. These enable the leads to swing clear of everything to two terminals on the bottom side of the gun-metal gratings. The two main terminals are on the opposite grating, from which point they may be very conveniently connected to the underground or overhead cables.

Fig. 2 is a two-pole machine, with a capacity of 200 kilowatts at 450 revolutions per minute. Three of these dynamos are now running in a large works in Lancashire, where the current frequently varies throughout the full range of the machines. The brushes, which are of copper, are not only absolutely fixed in one position throughout the full variation of the load, but even when it is exceeded by 20 or 30 per cent. Notwithstanding this overload, the dynamos, it is said, run sparklessly and without trouble.

Surface-Box Explosion.—A slight explosion occurred at about 10:30 o'clock on Wednesday morning, at the Bow-street end of Wellington-street. The cover of a pavement surface-box belonging to the Metropolitan Electric Supply Co. was blown 2ft. or 3ft. in the air. No injury was done, and no disturbance to the supply took place, the station staff being in ignorance of the occurrence until word was brought them. The cables to the surface-box are run in lead-jointed iron pipes, and it has not transpired how the gas was fired. Sensational reports of the explosion were published in yesterday's papers, but these were quite inaccurate. Messrs. Callenders are making a trench for mains in close proximity to the spot, and it was no doubt the appearance of the roadway that caused the impression that the explosion had ripped up several feet of it.

ELECTRIC MOTORS.*

The advocates of electricity as a motive power are at once numerous and influential; perhaps more numerous, however, than influential. The lack of influence arises from the suspicion that those who write papers, and advocate in the course of discussions the use of electricity for driving machinery of all kinds, are more or less prejudiced in favour of the system whose all but universal adoption they urge. There is so much good in electricity as a distributing agency, that it is to be deplored that enthusiasts overdo its advocacy. They protest over much in its favour. They fly too far heavenward, and we think it is about time that a word was said which may bring them to understand that, after all, the world of manufacturers and engineers wants something more than a machine or a system which is mechanically or scientifically perfect. The world, in a word, is sufficiently Philistine to measure the merits and demerits of electricity as a motive power on a commercial basis. Crudely stated, we want to know which is the more economical method of driving lathes or looms, electricity or the old-fashioned belts and lay shafts. Unfortunately this is a species of information that exists in extremely small quantities, or else is carefully treasured up for private use. It is next to impossible at this moment to obtain any trustworthy and complete information on a subject of very great importance; and we confess that we write now mainly in the hope of eliciting some statement of facts and some expression of opinion from our readers which may help others to attain to a right conclusion on the question.

It goes almost without saying that we have nothing to do in this connection with such installations as that at Niagara. Our lack of information does not extend to cases where power has to be transmitted over great distances in order that a huge waterfall may be utilised. Such water plants as those in the United States must be limited in number. We are concerned with much smaller and much more numerous things. A mechanical engineer, for example, requires, say, 300 I.H.P. to drive his shops. They are new shops. Shall he put up shafting and use pulleys and belts, or shall he dispense with the shafting and drive his tools with electric motors? Either will do, and do well. He has only one question to consider—which is the cheaper method of distributing the power of the engine? What are the details of this problem? In the first place, it is clear that the engine will have to be bought and supplied with steam, no matter what the system of distributing the power may be. To begin with, the power must be had. The first cost of the engine will be, let us say, £500. To this must be added the cost of the dynamo or dynamos. We do not think we shall be far wrong if we say that the price of this portion of the plant will be at least equal to that of the engine; we could mention cases in which the dynamo has cost very much more than the engine, but we do not wish to raise difficulties. The cost, then, of engine and dynamo is, say, £1,000. Next we want the motors and the wiring and the switchboard, &c.; these things will cost at least another £500; that is to say, the ultimate first cost of the whole plant will be about equal to that of three steam-engines. On the other side, we must put the cost of lay shafting, belting, and pulleys saved. It will not be easy, we think, to pursuade engineers that these represent anything like the first cost of the plant required to distribute power electrically, and it is well to bear in mind that the electric motor does not always wholly dispense with belting. Indeed, it is a question much discussed whether every machine ought to have its own motor or only every group of machines. So far as we can see, then, the cost of the driving plant in shops worked by electricity must be very much greater than the cost of the usual plant. The capital invested is larger. How much larger, it is by no means easy to say. We have found it practically impossible to get any precise comparative figures. If our readers can adduce some derived from actual practice, they will do good service by sending them to us for publication. It is quite possible that the figures do not exist in an available form. But if they do not, then engineers must remain very much in the dark as to the commercial value of the new system of power distribution. For the first cost is a very important matter, which not only deserves, but is sure to have, the fullest consideration. It may be worth while here to add, that in one case which has come recently under our own knowledge, a leading firm of engineers, adding largely to its shops, has, as the result of a very careful inquiry, resolved to use shafting and belts in its new shops instead of electricity, the first cost of the latter appearing to be out of proportion to the advantage secured. Our own position is very easily stated. We are familiar with most of what has been said and written on electrical driving, and we feel that information is still lacking on many points which are vital. In the first place, writers on the subject are for the most part either electricians or enthusiasts, and in neither case competent to give a perfectly dispassionate opinion. In the second place, comparisons are constantly drawn in favour of electricity, which are based on inadequate or unfair data. Thus we are told that in such and such a shop, the power utilised in running the diverse machinery is not more than 30 per cent. of that given out by the engines, and that the substitution of electricity for shafts and belts has effected a great saving. This is, of course, what we should expect; but it remains to be proved that in modern shops fitted up in the best way, there must of necessity be a waste of 70 per cent., or even half 70 per cent. of the power developed on the engine crank shaft. Electrical driving is, within limits, a great mechanical success. It is mere waste of time in the present year to set about proving that it is. We have quite got beyond that. What we want to know now is how much it costs? We do not require to be told anything about the extreme handiness of electricity; of the convenience with which it can be used here, or there or anywhere. All this and much more we concede; but there must be something to pay for all this, and we want to know how much. Are there any data available which let us know how much less money will have to be spent per annum in distributing 500 H.P. electrically over a factory, than would be needed if belts and pulleys of the best type were used? We say of the best type, because we must compare like things with like; and as all the electrical plant must be in new and in splendid order, it is only fair to assume a like approach to perfection in the older installation.

Engineers who are not electrical specialists are disposed to think that electricians press their advocacy a little too far and without discrimination. The Heilmann locomotive is a case in point. We have a powerful locomotive with its boiler mounted complete on a frame, and the engine, instead of turning driving wheels, turns a dynamo which supplies current to certain motors which cause the rotation of the driving wheels. It is claimed that the steam can be generated on this system, and used with much more economy than is possible with the normal methods; but even if we conceded that the cost of fuel per horse-power hour was less with the Heilmann locomotive than it is with the ordinary locomotive, nothing would be gained, for the simple reason that the cost of working locomotives is never expressed in terms of pounds of coal per horse-power hour, but in terms of pound of coal per train mile. So far as our information extends, the Heilmann engine has entirely broken down in this direction, however successful it may be in other respects. The news of an extension of the Heilmann system comes to us from the United States. We are told that a Mr. Painton has interviewed Messrs. Cramp with a view to the construction of a torpedo destroyer 250ft. long, 24ft. beam and 1,000 tons displacement. She is to be a great improvement on the Turbinia. The defect of that vessel is, that she runs her screws too fast. Mr. Painton gets over the difficulty with the aid of electricity. His boat is to be fitted with De Laval turbines, which will drive 85 tons of dynamos, which will supply current to motors on six screw shafts, each carrying three screws, and making 2,500 revs. per minute. Whether the "85 tons of dynamos" includes the motors or not, we are unable to say. The weight of machinery and ordnance is put down as eight tons. There is no reference made to boilers, which will have to supply 10,000 H P. of steam. The guaranteed speed of the boat is 40 knots. According to a correspondent of the *Globe*, Mr. Edwin S. Cramp has said of Mr. Painton's boat:—"Is not only in every way feasible, but a decided improvement on the Turbinia. It seems to me that there will be decided economy in fuel and steam, the employment of a dynamo to run the propeller shafts is a decided gain, and the greater distribution of power through six sets of propellers is good. It is an adaptation, I should suppose, of the Parsons turbine system. It is somewhat of a wonder that Mr. Parsons himself did not apply his invention in this way instead of directing his turbine power at once to the shaft. There must be less vibratory movement." It is suggestive that while Mr. Cramp admits that he would like to see the American Government try some experiments for Mr. Painton, he is careful to explain that his own firm does nothing in that way. For ourselves, we are audacious enough to say that to use dynamos and motors simply to reduce the speed of the shaft of a steam turbine sufficiently to suit a screw propellor is absurd; and we hold that Mr. Parsons knows what is and is not right in marine propulsion far better than Mr. Painton. We do not wish to imply that Mr. Painton's scheme finds favour in the eyes of reponsible electricians, but we feel certain that an expression of their opinion on such matters would be some service just now.

* From The *Engineer*.

Students' Visits to Works.—The October number of the *Bulletin* of the Société Internationale des Electricians contains an illustrated account of a trip to Switzerland made by the students of the Ecole Supérieure d'Electricité during the last Easter holidays. Eight days were spent in Switzerland, during which time no less than 18 works were inspected. The report is compiled from notes collected by the students themselves.

CORRESPONDENCE.

SHOREDITCH DUST DESTRUCTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am at a loss to understand Mr. T. W. Baker's attack upon the above scheme, especially when viewed in the light of the fact that Mr. Baker submitted a scheme to our Vestry for dust destruction, in conjunction with the electric light, in 1893; but the Vestry, with but few dissentients, rejected it. Is it a bid for cheap notoriety? Or is Mr. Baker's criticism the justification of his own scheme, for he states, "I do not infer, or wish to be understood, that all dust destructors are, or will be, financial failures?" Or is it the outcome of his chagrin that a more successful engineer should be in the happy position of being the first to successfully instal an electric light and dust destruction combined scheme?

Your contemporary *London*, having facts at their disposal, cleverly answers this attack in their last issue, for it must be known to you, Sir, that, as well as in your journal, Mr. Baker's letter appears simultaneously in *London*, the *Contract Journal*, the *Electrical Engineer*, *Lightning*, and the *Hackney Express* of this week, and no doubt there are more to follow; and I am put to the trouble, for the benefit of the many who are desirous of knowing the truth of our scheme, to reply to this attack.

As *London* points out, the basis of Mr. Baker's calculations of financial results falls to the ground in the face of the fact that he has taken our Vestry's financial reports, which only give accounts up to March this year, and is based upon a 12 months' expenditure with a nine months' income, the first quarter of which is invariably a heavy loss to any undertaking. Mr. Baker very ably connects the two schemes, the sale of electricity and the destruction of dust, and asks which is correct, the Vestry clerk's stated profit of £1,268. 17s. 9d., or Mr. Baker's supposed total loss of £1,522. 16s. 7d. Well, I emphatically state not Mr. Baker, and the Vestry clerk is correct so far as he goes, but from my point of view he does not go far enough. I will state here, and within the course of a few weeks justify my statement, as my committee's report on this matter will shortly be before the Vestry, and when it has passed that Board it can be made public. On our combined scheme we made a profit in the first year's working, after making all allowances, of £2,000 net.

This is as emphatic as I can put it, although probably Mr. Baker will again say "I note no amount for depreciation is allowed." I sincerely hope there never will be, because it must be remembered that we are paying back something like £5,000 per annum interest and capital on these undertakings, which means that in 30 years the dust destructor and electric lighting station will become a valuable freehold asset. That being so, where is the need of depreciation with the maintenance charges included in our estimates year by year. Further, I might add, as *London* reminds me, that the London County Council have practically verified the figures I have given you. Their valuer, in valuing us for assessment, went fully into these figures and based our assessment upon a profit of £1,800.

I cannot, without violating my position as Chairman of this Committee, give you details of the Scavenging Committee's figures, but they will all be included in the report I have mentioned, which I know is being anxiously awaited throughout the whole country, and which I venture again to say will give the satisfaction that this phenomenal scheme deserves.—Yours, &c.,

H. E. KERSHAW,
Chairman of Electric Lighting Committee.

Shoreditch Vestry, Oct. 24, 1898.

[We have also received a letter from Mr. H. Mansfield Robinson, the solicitor and clerk to the Shoreditch Vestry, covering to some extent the same ground as Mr. Kershaw's communication. He states, in addition:—"Mr. Baker's case consists of showing that the figures in my report (p. 2) do not harmonise with the surveyor's report and the electricity and destructor accounts. My statement that the 'destructor has also succeeded in destroying the whole of the dust in this parish, and *more besides*, up to a total of 18,842 tons *in nine months*' (p. 2) is not inconsistent, as Mr. Baker suggests, with the surveyor's statement at p. 188, that '*during the year*' 18,878 tons were collected by the scavenging department, as the latter figures refer only to the refuse of Shoreditch, whereas my figures expressly include 'more besides,' such as parish refuse from St. Luke's and trade refuse from the City sent to the destructor and not collected by the scavenging department at all. Again, my figures as to the coal burned were expressly stated to be for nine months, and were taken from the revenue account (p. 361), whereas the conflicting figures at pp. 350 and 323 of the accounts are headed in large type as 'accounts from March 25, 1897, to March 25, 1898,' and Mr. Baker, as an engineer, ought to know that it takes many weeks slow firing to prepare a destructor and make tests, &c., before steam raising can be attempted. He makes the same mistake in the dust destructor maintenance cost by comparing my figures for nine months with those for a year in the accounts. . . . The increase in the stokers' wages over the contractor's estimate is due to the Vestry adopting three shifts of eight hours each in place of the two shifts of 12 hours each, which were reckoned by the contractors." . . .—ED. *E.*]

LEGAL INTELLIGENCE.

The following causes are entered for trial at the Royal Courts of Justice during the present sittings:—

CHANCERY FINAL APPEALS.

Vestry of St. Mary, Battersea, v. *the County of London and Brush Provincial Electric Lighting Co.* (*Limited*).—Appeal of defendants from the order of Sir Francis Jeune, dated April 21, 1898.

Mica Insulator Co. v. *the Electrical Co.* (*Limited*).—Appeal of plaintiff Company from order of Mr. Justice Kekewich, dated June 30, 1898.

Castner-Kellner Alkali Co. (*Limited*) v. *the Commercial Development Corporation* (*Limited*).—Appeal of defendants from the order of Mr. Justice Bigham, dated Aug. 3, 1898.

QUEEN'S BENCH—FINAL APPEALS.

National Telephone Co. (*Limited*) v. *the Commissioners of Inland Revenue*.—Appeal of the Telephone Company from the judgment of Divisional Court, dated Dec. 14, 1897.

CROWN PAPER (Divisional Court).

Holliday v. *the National Telephone Co.*—Defendants' appeal from decision of Judge of the City of London Court.

CHANCERY DIVISION.

Before Mr. Justice North.—*Bristol Tramways Carriage Co.* (*Limited*) v. *the National Telephone Co.* (*Limited*). Cause for trial without witnesses.

Before Mr. Justice Stirling.—*National Co. for Distribution of Electricity, &c.*, v. *Gibbs*. Action and counter-claim with witnesses.

Before Mr. Justice Kekewich.—*Holophane* (*Limited*) v. *O. Bernd and Co.* (*Limited*). Witness action.

Holland v. *Chelsea Electricity Supply Co.* (*Limited*).—Action without pleadings.

Apostoloff v. *The Apostoloff Automatic Telephone, &c., Co.* (*Limited*).—Action with witnesses.

QUEEN'S BENCH DIVISION (Non-Juries).

Russell v. the London Electric Omnibus Co. (*Limited*).—Contract.

New Telephone Co. (*Limited*) *v. City of London Electric Lighting Co.* (*Limited*).—Contract.

Pearson v. Wilson Hartnell.

In the Leeds County Court, Mr. Reginald Hewitt Pearson sued Mr. Wilson Hartnell, electrical engineer, Leeds, under the Employers' Liability Act, to recover £210. 12s. damages and compensation for an accident alleged to have been due to negligence of defendant's foreman. It appeared that plaintiff was taken into defendant's service on Feb. 3, 1897, on the understanding that he was not to be bound apprentice, and that he was to receive no wages for the first three months, but 5s. a week after that period. On June 3, in this year, he was called upon by a foreman named Broughton to assist in removing an armature on to a trolley. In lifting the heavy piece of iron, the rope slipped at Broughton's end, and two of the plaintiff's fingers were crushed, one of them being permanently disabled. It was maintained by plaintiff that the lifting should have been done by means of the Goliath crane, which was adapted for heavy work. On plaintiff subsequently applying for compensation, he received a letter from the manager disputing liability on the ground that he "was not a member of the working class," that his position was not that of a serious workman, that he had had no premium to pay and had been employed as an improver, and certainly had not been retained for any useful service he had rendered. A statutory defence was set up to the effect that plaintiff had not given notice to the defendant of the accident within six weeks of the occurrence pursuant to the provisions of the Employers' Liability Act. His Honour held that sufficient notice had been given, and that if it had not been sufficient he had power to amend it. The further hearing was then adjourned.

Digitized by Google

POLICE INTELLIGENCE.

At Bow-street (London) Police Court, on Monday, John Limbrey Higgs, of Delahay-street, Westminster, appeared to a summons charging him with committing perjury during an examination in respect to the affairs of the I.E.S. Accumulator Co.

Mr. Avory, for the prosecution, said defendant appeared during recent years to have been engaged in company promoting, and was now charged with having committed wilful and corrupt perjury in his examination in respect to the affairs of the I.E.S. Accumulator Co., in swearing that a mortgage deed, secured to a Mr. John Walton, for £1,200, dated May 9, 1894, had been paid off and satisfied prior to Aug., 1895. This mortgage related to a licence to work the Theryc-Oblasser accumulator patent. In Dec., 1893, defendant agreed to purchase this licence for £2,000, and in the following January promoted a company (the Universal Electrical Lighting Co.) to obtain the purchase money and work the patent. Only £1,200 was subscribed to this company, and defendant accordingly mortgaged the licence to Mr. Walton for a second £1,200. The licence was not assigned to the company, but in June, 1895, defendant entered into an agreement with Mr. Mann, as trustee for a new company, to buy this licence for £2,000. This company (the I.E.S. Accumulator Co.) was duly formed, with defendant and his father-in-law as two of the directors. The purchase of this patent did not appear on the prospectus, but at a board meeting in July, 1895, at which defendant was present, the directors agreed to acquire the patent, and to pay him £2,000 for it, and this sum was actually paid to him by cheques in 1896. In 1897 the company was in difficulties, and in Oct. called an extraordinary meeting to consider voluntary winding-up. Some of the shareholders opposed this motion, saying that certain practices had come to their knowledge which required fuller investigation, but the voting power of the directors was sufficient to get the motion carried. In March, 1898, however, an order was obtained for the examination of defendant and other directors of the company, and then defendant, being obliged to admit the mortgage of 1894, in order to justify his subsequent sale of the licence, swore that the mortgage was paid off before Aug., 1895. As a fact, the mortgage was not paid off until Oct., 1897, when defendant found the money because he was moving to have a receiving order against him rescinded, and to satisfy the registrar that he had paid all his debts he had to produce this mortgage and the receipt, dated Oct., 1897, so that he had made two conflicting statements.

At this stage the hearing was adjourned for a fortnight, Mr. Denniss, who represented the defendant, announcing that he should be prepared to prove that defendant had not received from the company the £2,000 purchase money for this patent.

At Exmouth on Wednesday Ernest James Thomas, *alias* Ward Thomas, described as an electrical engineer, of Laira, Plymouth, late of Exeter, was charged on remand with obtaining goods by false pretences from various firms, including the Telegraph Manufacturing Co., Helsby, and the Gandy Belt Manufacturing Co. Mr. Beale, who prosecuted, stated that the prisoner had sent out headed note paper to various firms wrongfully representing himself to be carrying on a genuine business. On the head of some of these letters he described his firm as the Western Counties Electrical Co., Barbican, Plymouth. Prisoner also wrote from Drayton House, Plymouth. In most of the letters the goods were asked to be sent on at earliest convenience. William Teglio said he was lessee of some stores on the Barbican, Plymouth, one of which was rented by the prisoner at a yearly sum of £10, but witness had not received his rent. William Furze, 3, Alderney-terrace, Plymouth, deposed to renting a store in Commercial-road, and directly over the one occupied by prisoner. The only business he ever saw carried on at prisoner's store was the cleaning of a dirty brass bracket. On the door was tacked a card bearing the words "Western Counties Electrical Company," and on another "All letters should be thrown over the door." Witness had seen prisoner frequently there, and had also seen railway vans bring a deal of goods, but they were never taken into the stores. Where they were taken to he did not know. Several witnesses proved the delivery of leather belting at the Exmouth Hotel in September, and subsequent delivery to prisoner. When apprehended at Laira, prisoner said: "Is that all; I can stand that like a man. I suppose it will be just the same as on the last occasion. I can plead under the Debtors' Act." Prisoner having been committed to the Assizes in respect to the charges in which the Gandy Belt Co. were concerned, evidence as to obtaining goods from two other firms was taken, and on both these charges the Bench committed prisoner to the Assizes. The remaining charges were heard yesterday (Thursday).

Lamp-holders for Meter-less Consumers.—In some districts small consumers whose quarterly bills for electrical energy could not support the burden of a meter rental are charged a fixed price per lamp per annum. The charge can take account of the possibility of exceedingly long burning-hours, but not of the honesty-factor of the consumers, the temptation to put in lamps of higher candle-power than those contracted for being very great. At Kingston, we believe, this difficulty was overcome by using locked holders, but a French firm of manufacturers has found a neater solution. The lamp-caps and holders are made on the bayonet principle, but with three pins and slots instead of two. These are placed in different relative positions for lamps of various candle-powers, so that only the lamp of the right size will fit the holder supplied for it.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition ready in November.*

"Practical Notes for Electrical Students."—By Messrs. A. E Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"Electromagnetic Theory."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s. *Nearly ready.*

Digitized by Google

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System o Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s. post free; abroad, 6s. 6d. Digest post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl. *In the Press.*

"THE ELECTRIC ARC."—By Mrs. Ayrton. *In the Press.*

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade. *In the Press.*

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael. *In the Press.*

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R. Cooper. *In the Press.*

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."—*In the Press.*

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The Electric Lighting committee of the *Salford* Corporation invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walness-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, by Dec. 1.

The Electric Lighting committee of the borough of *Middlesbro'* require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers and accessories, mechanical stokers, feed pumps, injector, economiser and electric motor; (*b*) slow speed steam dynamos and accessories; (*c*) condensing plant and pipe work; (*d*) overhead travelling crane; (*e*) switchboard and instruments; (*f*) accumulators; (*g*) trenching, cables, &c.; (*h*) meters. Further particulars are set out in an advertisement in another column. Specifications, &c., may be obtained at the offices of Mr. R. Hammond, consulting engineer to the Council, 64, Victoria-street, Westminster, S.W., after Nov. 2. Tenders to the town clerk (Mr. Geo. Bainbridge), Municipal Buildings, Middlesbro', by Tuesday, Nov. 29.

The *Redditch* District Council invite proposals for the wiring of premises on the hire-purchase or deferred-payment system. Further particulars are set out in our advertisement columns, and tenders are to be addressed to Mr. J. A. McMullen, M.I.E.E., consulting electrical engineer, Hornchurch, Essex.

The *Hornsey* District Council invite tenders for the supply and erection of electric lighting plant at the Council's central public library, Tottenham-lane, Hornsey. Specification, &c., can be obtained of Mr. E. J. Lovegrove, engineer to the Council. Further information is contained in an advertisement elsewhere, and tenders must be deposited with the clerk (Mr. F. D. Askey), Southwood-lane, Highgate, London, N., by 4 p.m. of Monday, Nov. 7.

The *Hornsey* District Council also invite tenders for the supply of 1,500 cast-iron telephone pipes and 30 telephone pit covers. Tenders to the clerk by Nov. 7.

The Corporation of *Barrow-in-Furness* invite tenders for the supply and erection of cast-iron lamp columns, arc and incandescent lamps, automatic switches and fittings. Some further particulars will be found in an advertisement elsewhere, and specifications, &c., can be obtained from the Municipal Offices, Barrow-in-Furness, or from Messrs. Kincaid, Waller and Manville, engineers to the Corporation, 29, Great George-street, Westminster, London. Tenders must be sent in to Mr. C. F. Preston, town clerk, Municipal Offices, Barrow-in-Furness, before noon of Monday, Nov. 14.

The *Belfast* Harbour Commissioners require tenders for the supply of nine iron lattice-built electric light masts, 70ft. high from the ground lines with suitable base. An advertisement on another page gives further particulars. Tenders must be sent in to Mr. W. A. Currie, secretary, Harbour Office, Belfast, not later than Monday, Nov. 14.

The *Edinburgh* Corporation invite tenders for the following plant for their electric lighting station in McDonald-road—(1) Marine type boilers and mechanical stokers, (2) engines and dynamos. The engines must be of the Willans or Belliss type. Tenders to the offices of the town clerk (Mr. Thomas Hunter), Town Hall, Edinburgh, by Nov. 14.

The *Sunderland* Corporation require tenders for an electric motor for pump driving. Tenders to the town clerk by 31st inst.

The *Leatherhead* District Council invite offers from engineers and others who are willing to take over their Electric Lighting Order (1898). Offers to Mr. W. J. Hodges, Council Offices, Leatherhead, by Nov. 21.

Tenders are invited for the supply and fixing of two engines and dynamos at the *Southampton* County Lunatic Asylum, Knowle, near Fareham. Tenders to Mr. John R. Wyatt, Knowle, by Nov. 16.

Tenders are required by the *Wimbledon* District Council for the supply, delivery and erection of transformers and accessories. Tenders to Mr. W. H. Whitfield, Wimbledon, by 5 p.m. Nov. 7.

The *East Indian Railway Co.*, Nicholas-lane, London, E.C., are about to introduce electrically-controlled block instruments on their system, and invite proposals for the supply of 18 instruments for nine blocks (for single line); 80 instruments for 41 stations (for double line), and six spare instruments. Tenders to the secretary by 1 p.m. of Nov. 23.

The Paving and Highways committee of the *Manchester* Corporation require tenders for the laying of a system of underground telephone pipes, &c. Tenders by 5 p.m. Nov. 8.

The Electricity committee of the *Nottingham* Corporation require tenders for the erection of a new electricity station. Tenders to town clerk by Nov. 4.

The *Harrogate* Corporation require tenders for supplying 18 cast-iron arc lamp-poles, with carriers. Tenders to the electrical engineer, Harrogate.

The Electric Lighting committee of the *Morecambe* District Council require tenders for supplying one Lancashire boiler, one 180 kilowatt continuous-current dynamo, three switch panels, two 40 kilowatt continuous-current transformers, long-range switches, short-circuiting switches, &c. Tenders to electricity works, Morecambe, by 31st inst.

The *Toronto* Board of Control require tenders for electric lighting plant, including (1) engine equipment, (2) countershafts and pulleys, (3) belting, (4) boilers, (5) feed pumps, (6) water and steam piping, (7) fuel economisers, (8) dynamos and station electrical apparatus, (9) arc lamps, (10) mast arms and lamp attachments, (11) poles and overhead circuits, and (12) conduits and cables. Plans, &c., from city engineer, and tenders to Board of Control, City Hall, Toronto, by noon of Nov. 9.

The *Spanish* Post and Telegraph authorities invite tenders for the concession to establish and work a telephone exchange in Cuenca. Tenders to La Direccion General de Correos y Telegrafos, Madrid, by Nov. 8.

Tenders are invited until Nov. 8 by the *Roumanian* Post and Telegraph authorities, Bucharest, for the supply of 16,000 porcelain insulators and 60 tons of 2mm. galvanised steel wire.

The *French* Post and Telegraph authorities invite tenders until Nov. 8 for the supply of four lots of telephone cable, and until Nov. 10 for 50 kilometres of paper insulated electric cable and 46 kilometres of gutta-percha-insulated cable. Tenders to le Sous-Secretariat d'Etat des Postes et des Telegraphes, Rue de Grenelle, 103, Paris.

TENDERS RECEIVED AND ACCEPTED.

The tender of Messrs. Victor Coates and Co. has been accepted by the *Belfast* Corporation for the supply of an additional mechanical stoker for the electricity supply works.

The *Bexhill-on-Sea* District Council have accepted the following tenders for the supply of electric lighting plant:—

R. Hornsby and Sons (water-tube boilers)	£1,748 10 0
W. H. Allen, Son and Co. (steam dynamo and balancer)	2,570 0 0
Chloride Electrical Storage Syndicate (storage battery)	1,020 0 0
British Insulated Wire Co. (underground cables and pipes)	5,958 0 0
British Insulated Wire Co. (arc lamps and posts)	665 15 6

The contract for the switchboard, for which eight tenders were submitted, has not yet been let. Twelve tenders in all were received for the boiler contract, 13 for the storage battery, 16 for the steam dynamo and balancer, seven for the cables, and eight for the arc lamps and posts.

The *Dewsbury* Town Council have accepted the tender of the Callender Co. for supplying an electric light cable at £1,396.

Tenders for wiring work usually display a remarkable difference between the highest and lowest amounts, but that this peculiarity is not confined to wiring tenders will be seen from the following:—The *Plymouth* Town Council have accepted the tender of the Newton Electrical Works for the supply of a 10 B.H.P. enclosed (ironclad) continuous-current motor, at £88. 15s. 6d. Sixteen tenders, varying from £88. 15s. 6d. to £205, were submitted.

Digitized by Google

The Works committee of the *Hull* Corporation have accepted the following tenders for the electric tramways department :—

Westinghouse Electric Co. (45 motor cars, each to carry 51 passengers), at £582 per car.

Siemens Bros. and Co. (20 double-deck trail cars, to carry 52 passengers), at £195 and £210 per car.

Westinghouse Electric Co. (two sprinkling cars), at £336 per car.

J. Carrick and Sons (overhead crane), at £228.

The committee have selected the Brill truck ; 30 of the motor cars are to be fitted with chilled iron wheels, at a reduction of £10 ; and the car bodies are to be divided amongst the different makes specified, in the proportion of Brush 30, Milnes 10 and Brill 5. The accepted tender is at £522. 10s. for Brush bodies, £536 for Milnes bodies and £586 for Brill bodies, the motors in all cases being made by the Westinghouse Co. In the case of the trailer cars, the committee recommend that, if Messrs. Siemens Bros. and Co. do not object to supply trailer cars without motor cars, their tender be accepted for ten by the Electric Railway Carriage Co., and ten by Messrs. Milnes and Co. Failing this arrangement, they recommend that the Westinghouse Co.'s tender be accepted for 20 Milnes' cars. Messrs. Siemens Bros.' tender was at £195 for cars built by the Electric Railway Carriage Co. and £210 for Milnes' cars. The Westinghouse Co.'s tender was at £215. As to the tenders for five open trailer cars, none of the designs submitted seemed to meet the committee's requirements, and the acceptance of the tenders for these and for the traversing platforms has been deferred.

The *Gloucester* City Council have accepted the tender of Messrs. John Gurney and Son for the erection of electricity station buildings, at £5,750.

The Tramways committee of the *Bradford* Town Council have accepted the tender of the Westinghouse Electric Co. for the supply of eight new motor cars and that of the Brush Co. for the supply of four trailer cars at £238 each.

The *Dundee* Town Council have accepted the tender of the Callender Co. for the supply of feeder mains at £1,374.

The *Bolton* Corporation have accepted the following tenders for electric tramway and lighting purposes :—

Mather and Platt (two 1,000 H.P. engines, two 600-k.w. generators, and two 25-k.w. boosters)	£14,905	0
Mather and Platt (two 500 H.P. engines, two 200-k.w. generators, and two 12-k.w. boosters)	8,886	0
British Insulated Wire Co. (mains for lighting)	3,640	0
British Insulated Wire Co. (feeders for tramways)	16,980	0
British Thomson-Houston Co. (overhead equipment, bonding and switchboard)	32,821	0
British Thomson-Houston Co. (switchboard for lighting)	976	15
Musgrave and Co. (boiler)	795	0

APPOINTMENTS VACANT AND FILLED.

The London County Council invite applications for the position of chief officer of tramways. Salary £1,500 per annum. Applications to the clerk, County Hall, Spring-gardens, S.W., by 10 a.m., Nov. 14.

The Shoreditch Vestry require a clerk of works to supervise the erection of a new battery room, boiler house, &c., at their electricity supply works. Salary £3. 3s. per week. Applications to vestry clerk, Town Hall, Old-street, London, E.C.

The Salford Corporation require a switchboard attendant. Wages 34s. per week. Applications to the electrical engineer (Mr. C. L. Turner), electricity works, Walness-road, Salford. See advertisement.

Messrs. Thomas Richardson and Son, Hartlepool, require a wireman for general wiring and repairing work. See advertisement.

Agents are required by Messrs. W. M. Still and Co., of 24, Charles-street, Hatton Garden, London, E.C., for the sale of the "Still" incandescent electric lamp in all parts of England. See advertisement.

Agents in this country are required by M. A. Larnaude for the sale of incandescent lamps of his manufacture. See advertisement.

Mr. T. H. Harvey has been appointed London traveller for the Johnson and Phillips Electric Cable Works, in the place of Mr. McKrell, whose connection with the firm ceased on 31st ult.

Mr. C. H. Robinson, of Oldham, has been appointed assistant at the electricity station at Dewsbury.

BUSINESS NOTICES.

The partnership hitherto existing between Leslie Miller and Maurice W. Woods, trading as Miller and Woods, manufacturing electricians, 2, Gray's Inn-road, Holborn, London, has been dissolved by mutual consent. Mr. Woods continues to trade at the above address as Woods and Co. Mr. Miller has taken premises at 93, Hatton-garden, E.C. The circular announcing the dissolution states that all debts owing by the firm have been settled, and that the outstanding accounts can be paid to either of the parties.

Owing to increased demand for the company's manufacture of telephones, the General Electric Co. have found it necessary to extend their premises by the addition of No. 92, Queen Victoria-street, London, where a special telephone department has been created, and where a large stock of telephones and telephone accessories will be kept. A considerable addition has also been made to the works at Manchester. The company point out that, while they do not undertake the installation of telephones, clients will receive all possible assistance to enable them to tender for telephonic installation work.

Mr. Henry Lyon, lately with D. Stewart and Co. (Limited), has commenced business in partnership with Mr. J. B. T. Crosbie, as consulting electrical and refrigerating engineers, at 240, Hope-street, Glasgow.

The address of the English Varley Duplex Magnet Co. (Limited) has been changed from the Strand to Lodge-lane, Derby.

Mr. Henry Edmunds has removed his offices from 39, Victoria-street, to 2, Queen Anne's-gate, Westminster, London, S.W.

We are informed that Mr. Claude W. Hill has resigned his position as manager to the Phœnix Dynamo Co. of Bradford.

BANKRUPTCIES, LIQUIDATIONS, &c.

Mr. Serge Berditschewsky Apostoloff, electrical engineer, 5, Fenchurch-street, E.C., and 25, Coniger-road, Fulham, S.W., London, has executed a deed of arrangement, with liabilities amounting to £5,540. 1s. 6d., and assets estimated to produce £14,785. 4s. 7d. The trustee is Mr. W. B. Keene, 3, Church-court, Old Jewry, E.C.

The statement of the liquidation of the Morecambe Electric Light and Power Co. shows that the receipts since the meeting in Feb., 1896, amounted to £3,423, the principal item being £2,718 from the Council for plant and undertaking. Expenditure amounted to £3,422, leaving a balance of 17s. 9d. The holders of debenture bonds, "A" series, will be paid in full, absorbing £2,052 ; and "B" series 3s. 5½d. in the £. No assets are available for either unsecured creditors or ordinary shareholders.

Claims against the London Metallurgical Co. (Limited) must be in by Nov. 7. Mr. J. D. S. Bogle, 91-93, Palmerston-buildings, London, E.C., is liquidator.

Claims against Geo. F. Rogers, electrical engineer, 41, Maxilla-gardens, Notting Hill, W., and 9, Great Winchester-street, E.C., London, must be sent to the trustee (Mr. E. B. Lumb), 85, Grace-church-street, London, E.C., by Nov. 7.

Messrs. Donald Enock and Eric C. Enock, electrical and general engineers, Coombe Works, Dartmouth, have executed a deed of arrangement. The liabilities are returned at £1,759. 1s. 9d., assets £1,990. 6s. 3d. Mr. A. G. Davey, Torquay, is trustee.

At the London Bankruptcy Court the public examination of J. Condict, company promoter and director, Broad-street House, E.C., has been held. Liabilities £31,314, assets of uncertain value. For many years prior to 1890 debtor carried on business in the United States as an engineer and contractor, but in that year came to London with a capital of £20,000, and became engaged in the promotion of companies. He acquired an interest in the London Electric Omnibus Co. (Limited) and other companies. Creditors treated as partly secured held shares to the nominal value of £52,126 in the Omnibus Co. Failure attributed to heavy depreciation in the value of these and other shares. Examination concluded.

A meeting of the creditors of Charles Henry Kitching, 20, St. Hilda-street, and carrying on business at 172, Beverley-road, and 42, Chariot-street, Hull, as electrical engineer and plumber, was held on Friday, at the offices of the official receiver. Debtor returns his gross liabilities at £3,296. 19s. 4d., expected to rank £2,284. 17s., assets £1,365. 13s. 10d., leaving a deficiency of £919. 3s. 2d. Failure attributed to want of capital and bad debts. Commenced business, trading under his own name and also as the City Electric Lighting Works, in March, 1896, with £200 borrowed capital. A committee of inspection was appointed.

Sale by Tender.—Notice is given in an advertisement on another page by Mr. J. H. Thornton, the liquidator of the National Company for the Distribution of Electricity by Secondary Generators (Limited), of the sale by tender of certain patents for secondary generators belonging to the said company, particulars of which will be found in the advertisement. Tenders have to be sent in to Mr. Thornton, 2, Warwick-street, Regent-street, London, W., by 12 noon of Monday, Nov. 28.

Sale by Auction.—Messrs. Henry W. Figg and Son, of 37, Upper Thames-street, London, E.C., will sell by auction on the premises, 48, Commercial-street, Whitechapel, London, E., on Wednesday next, Nov. 2, at one o'clock, the stock in trade and electrical fittings of J. Goodman and Co. (in liquidation). Some further particulars will be found in an advertisement on another page.

Personal.—We are informed that Mr. Slater Lewis, engineer and general manager to Messrs. P. R. Jackson and Co., will shortly pre-

Digitized by Google

sent a Paper on the subject of dynamo design to the Institution of Civil Engineers.

Instrument Catalogue.—Sig. C. Olivetti, of Ivrea (Italy), forwards a price list of electrical instruments. We notice two galvanometers on the moving coil principle of novel design, and a candle lantern for use with a celluloid transparent scale. Sig. Olivetti also supplies a Daniel cell with an arrangement for decantering off the acid when the battery is not in use, and makes a speciality of hot wire ammeters and voltmeters.

Insulated Wire and Cables Catalogue.—The past few years have witnessed a great improvement in the supply of textual matter in the price lists and catalogues of the leading makers of electrical plant, apparatus and materials, and the up-to-date manufacturer is no longer satisfied to leave the buyer of his goods in ignorance of the special features of his own particular make of electrical specialities. This feature is well shown in trade lists which have recently come under review in our columns, and a catalogue just to hand from Messrs. Connolly Bros. (Limited), of Blackley, Manchester, emphasises the point. The descriptive matter of the catalogue has been re-arranged and great care has been taken, in compiling the list, to give just the information required in as clear a form as possible for easy reference without any superfluous matter. Attention is called to the conspicuous success which has attended the placing on the market of "Blackley" tape, which, it is claimed, has earned a world-wide reputation. The information given covers the entire range of regular makes of electric wires and cables.

Machinery Catalogue.—The Southgate Enginering Co., of New Southgate, near London, forward a neatly-printed machinery catalogue, showing illustrations of lathes and other plant for turning and finishing projectiles. At a time when war is so much in the air the catalogue is opportune.

"Trades' Unionism Rampant."—Upon this subject we have received the following letter from Messrs. Calvert and Co., which must, so far as we are concerned, terminate the dispute :—

"TO THE EDITOR OF THE ELECTRICIAN.

"SIR: We cannot allow the letter of Mr. Sims in your last issue to remain unchallenged. Mr. Sims, in his former letter, said we were paying our men 22s. to 30s. per week, now he admits we are paying them the union rate of 9d. per hour, which means 39s. at 52 hours per week. This is Mr. Sims' first misstatement. Further Mr. Sims says that after certain of our men joined the union 'Messrs. Calvert refused to allow them to start because they were members, so that Messrs. Calvert have only themselves to blame for any delay that may occur.' This statement is absolutely false, and a man in Mr. Sims' responsible position ought to make it his duty to get at the facts of a case before making public misstatements, and causing unnecessary bad feeling all round.

"The facts are as follows: Mr. Rowbotham, the builder, was told by his bricklayers, &c., that they would strike unless Calvert's electrical workmen joined the union. We had no objection to our men joining the union, or to employ union men, having several in our employ at the present time; but we would not agree to bind ourselves to carry out the Bethnal Green contract under union tyranny (for reasons given below), and Mr. Rowbotham then shut our men out of the building.

"We again applied for admission, but were refused, and on leaving the works met some of our men, amongst others one named Fisher, who informed us that he and two others out of six skilled wiremen had joined the union. Our manager on the work (Mr. McInnes) informed him that unfortunately we were shut out, but he would try to find him another job. This is a very different tale to our refusing to allow the men to commence because they had joined the Union. This is Mr. Sims' second misstatement.

"Allow me [the writer is Mr. James Calvert] to take this opportunity of personally stating that I have always been a strong defender of Trade Unionism; but I hold that when it is demanded that I shall pay a fully skilled painter £2 a week to brush a little shellac on a piece of casing which can be quite as well done by a 15-year old boy getting 6s. a week, then Trades Unionism becomes gross tyranny."

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Oct. 19 to Oct. 25, with the ports of destination :—

Argentina—Buenos Ayres, £56. *Australasia*—Adelaide, £12; Albany, £121; Brisbane, £53 (telegraph wire); Melbourne, £296 (telegraph material); Otago, £51; Sydney, £50; Wellington, £2,710. *Belgium*—Ostend, £30. *Canada*—Santos (B.C.), £120. *Ceylon*—Colombo, £53. *China*—Shanghai, £314; Tientsin, £741 (telegraph material). *Denmark*—Copenhagen, £400. *Ecuador*—Limon, £12. *France*—Marseilles, £19. *Germany*—Bremen, £240; Hamburg, £654. *Holland*—Amsterdam, £10; Rotterdam, £4,498. *Hong Kong*, £1,025. *India*—Bombay, £105; Calcutta, £657; Madras, £19. *Japan*—Yokohama, £1,645 (telegraph material). *Madeira*—£122. *Russia*—Batoum, £50; Odessa, £70 (telegraph material); St. Petersburg, £175. *South Africa*—Cape Town, £176; Durban, £192; East London, £100. *Spain*—Malaga, £22. *Straits Settlements*—Singapore, £25. *Sweden*—Gothenburg, £256; Stockholm, £1,216 (including £792 telegraph material). *West Indies*—Trinidad, £36. Total £16,331, against £29,112 in the corresponding week last year (Oct. 20 to 26).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Amsterdam.—The Municipal Council have decided to undertake the working of the city tramways as from Jan. 1, 1900, the date of the expiry of the concession of the Amsterdam Omnibus Co., whose dividend for 1897 amounted to 9·8 per cent.

Birkenhead.—The Town Council's proposed tramway extension bill was under discussion on Wednesday, and approved. Power for adopting electric traction on the whole of the tramways is being sought.

Bognor.—Electric lighting powers are to be obtained by the District Council, who have retained Messrs. W. T. Chadwin and W. T. Pressland, as consulting engineers, at a fee of 30 guineas. The Council think that by adopting electric light a saving will be effected in the cost of public lighting. It is announced that a syndicate is endeavouring to obtain powers to construct a light (electric) railway between Bognor and Chichester, and it is possible that both schemes may be combined.

Bolton.—The Corporation have let contracts for the electrical equipment of the local tramways and for the extension of the electric lighting undertaking. The scheme is expected to cost nearly £250,000. The overhead trolley system has been decided upon, and 70 cars will be put on the lines, which will equal 30 miles of single track.

Bradford.—A special meeting of the Corporation will be held this (Friday) evening, when a report will be presented by the Gas and Electricity committee recommending that borrowing powers be sought to enable the electricity department to purchase and let on hire electric motors, fittings, &c., and also that two new 300 H.P. steam dynamos be ordered at an estimated cost of £4,000.

Brighton.—The Town Council last week upheld the decision of the General Purposes committee to oppose all schemes for the construction of electric tramways in the town. It was, however, stated that the Council would probably bring forward a scheme of their own next year.

Bristol.—The Constitutional Club, which has been undergoing decoration and repair, is now lighted electrically.

British Chamber of Commerce, Paris.—A lengthy report is just issued by this chamber covering the year 1897. Taking advantage of the occasion of the 25th anniversary of the foundation of the chamber a mass of comparative statistics of Anglo-French trade for the 25 years, 1872-1897, have been prepared and published. Those interested in the trade between France and England will study this volume of over 300 pages closely. There are 13 complete tables on trade, which have been specially drawn up for this report from documents supplied by the French customs.

Bury St. Edmunds.—It is reported that the Local Government Board have declined to receive the deputation recently appointed by the Town Council to urge the Board's sanction to their original electric lighting scheme.

Chelsea (London).—The Vestry are recommended by the Lighting committee to apply for a provisional order for the Kensal Town portion of the parish.

Cheltenham.—The Town Council decided on Monday to apply for a provisional order to extend the electric lighting area so as to include the whole of the borough.

Coatbridge.—Bailie Lavell, the convener of the Lighting committee, announces that he is prepared to propose to the Town Council the advisability of purchasing the undertaking of the Scottish House-to-House Electricity Co., as he believes that the works would be more successful in the hands of the Corporation.

County Council's Regulations as to Outside Lighting.—Last week, the Manufacturers' Section of the London Chamber of Commerce considered the proposed bye-laws of the London County Council for the regulation of lamps over structures overhanging the footway outside the City. It was stated that, if carried out, the regulations would involve considerable expense to shopkeepers and others, without any compensation, and would practically entail the total abolition of outside lighting, the impossibility of effectually displaying goods, increased risk of fire through interior lighting, and the refitting of windows and reconstruction of premises. It was unanimously resolved to call a meeting of the retail members of the Chamber to consider the whole matter, and take such action as was deemed necessary in opposing the Council's proposed bye-laws.

Darjeeling (India).—Complaints are made of what is described as excessive charges for electric current by the municipal authorities of Darjeeling. The cost per unit is said to be 12 annas.

Derby.—The Parliamentary committee have now arranged terms with the local Tramways Company for the purchase of the tram lines in the town. As soon as the undertaking is taken over by the Corporation it is probable that electric traction will be introduced.

Dewsbury.—The Town Council has decided to apply to the Local Government Board for sanction to borrow £9,060 for increasing

Digitized by Google

the voltage of their system of electricity supply, for extending the mains into the residential part of the borough and putting down an additional steam dynamo, &c.

Dockyard Lighting.—The Grangemouth Dockyard Co. have decided to adopt electric lighting, and the contract has been placed with Messrs. T. Laurie and Co. About 300 lights, including 14 arcs for outside lighting, will be required.

Dudley.—The Town Council have sanctioned the British Electric Traction Co.'s application for leave to reconstruct the tramway from the depôt in Birmingham-road to the borough boundary at Hart's-hill for electric traction. The Company have practically completed the reconstruction of the line from Brierley-hill to Stourbridge.

Dumfries.—The Town Council resolved on Monday to obtain a provisional order.

Durban.—The directors of the tramways company have agreed to accept the offer of the Corporation for the purchase of the undertaking for £114,000. The Corporation has instructed the borough engineer and the borough electrical engineer (Mr. Hadfield) to proceed to England to investigate the question of electric traction and prepare specifications for converting the whole of the lines.

Ealing.—The equivalent number of 8 c.p. lamps connected to the Council's electric lighting mains is 18,276, and an additional 1,000 are awaiting connection. The capital expenditure to date is £57,803. There was a deficiency on last year's working of £498.

East Barnet.—The District Council have decided to obtain a provisional order.

Farnham.—The District Council have retained Mr. F. J. Warden-Stevens to advise them on the public electric lighting of the district.

Faversham.—The Town Council have decided to place the police station and the residences of the members of the fire brigade into telephonic communication.

Fleetwood.—The contract for the supply and laying of cables and mains for the Fleetwood and District Electric Light and Power Syndicate is being executed by Messrs. Johnson and Phillips. It is reported that the demand for current is satisfactory.

Forthcoming Books.—Our readers may be interested to learn that Messrs. Archibald Constable and Co. will publish early in November "The Life of the late Sir Charles Tilston Bright, C.E., M.P.," wherein is included the story of the first Atlantic cable, the first telegraph to India and the colonies, and the early land telegraphs of the United Kingdom. The book is written by Mr. E. B. Bright and Mr. Charles Bright, F.R.S.E., brother and son respectively of the subject of the memoir. The book, which contains many full page and text illustrations, as well as photogravure plates, maps, charts, &c., will be published in two volumes, demy 8vo. The price, which before publication will be £2. 2s. net, will be raised after the date of publication to £3. 3s. net.

Gateshead-on-Tyne.—The Parliamentary committee of the Corporation presented a report at Wednesday's meeting which stated that an interview had been held with a representative of the Electrical Power Distribution Co., with reference to the company's proposed application for a provisional order. The company were prepared to pay the cost of obtaining an order for the whole of the borough, and the Corporation would be entitled to purchase the undertaking on two years' notice at any time after 10 years at a value to be fixed by independent valuers. The company would be compelled to supply current for street lighting when required at 2d. per unit after the first hour at 7d. The price to private consumers would be 2½ per unit after the first hour at 7d. To consumers in artisans' dwellings or flats current would be supplied at the all-round inclusive price of 6½d. per unit, this price to cover free wiring and meter rent. Current for power purposes would be supplied at 2d. per unit after the first hour at 7d. The system of supply would be low-tension continuous current. The committee recommended the Council to sanction the company's application, and this was agreed to after discussion.

Gravesend-Northfleet Electric Tramways.—The proposals of the Drake and Gorham Electric Power and Traction Co. for the purchase of the local tramways, for the extension of the system, and for the introduction of electric traction, meets with much local favour. Already the Northfleet Council have conditionally approved the scheme, and it is more than probable that the Gravesend Council and other authorities interested will adopt a similar course.

Hampstead (London).—At the end of Sept. there was an equivalent of 71,367 8 c.p. lamps connected to the Vestry's electric lighting mains, an increase of 2,840 for the month.

Hawthorn (Victoria).—Some time ago the Municipal Council advertised for tenders for electric lighting plant, but as there was considerable opposition to the Council engaging in the business of electricity supply a poll of the ratepayers was taken upon the question. This poll has resulted in giving a majority to the opponents of municipalisation, and it is probable that the work will now be undertaken by a company.

Hereford.—The Electric Lighting committee are making investigations into the cost of putting down electric lighting plant. At present, the members seem to favour gas-driven plant, but no decision will be arrived at until reliable estimates for a steam power plant are obtained.

Hill of Howth Tramways.—At Dublin, on Tuesday, Mr. Ryan, C.E., arbitrator for the Board of Works, heard objections to his draft award in respect of the property taken by the Great Northern Railway Co. of Ireland under the powers obtained by them for constructing an electric tramway from Sutton to Howth. The sitting was occupied in hearing evidence on behalf of the objectors.

Hornsey (London).—The District Council have definitely decided not to entertain any proposal from a private company for the supply of electric current in the Hornsey district.

Hospital Lighting.—The electric light is to be installed at the North Eastern Hospital for Children, Goldsmith-row, Hackney-road, London, N.E. The cost of the work is being borne by Mr. C. G. J. Port.

Huddersfield.—There is an equivalent of nearly 50,000 8-c.p. lamps connected to the mains of this station.

Hull.—The Council have adopted the recommendation of the Works committee to oppose the proposal to construct an electric tramway from Hull to Hessle.

Institution of Engineers of the River Plate.—Some time ago Mr. E. Danvers, of Buenos Ayres, took a prominent part in the formulation of a scheme for the establishment of an institution of electrical and mechanical engineers of the River Plate, and on July 11 last a meeting was called for the purpose of drawing up a memorandum of association, rules, &c. It had originally been intended to confine the institution to electrical and mechanical engineers, but as several civil engineers had promised their support it was decided that all members of the engineering profession should be included in the title of the new society, which has therefore been established as the Institution of Engineers of the River Plate. At the meeting, Mr. Danvers submitted the rough draft rules, which were discussed and modified in accordance with the views of the gentlemen assembled, and ultimately Mr. Danvers was requested to submit the corrected rules and articles of association in order that copies might be supplied to the initiators of the movement for final signature. A meeting was held on Sept. 29 to confirm the rules and to elect a council. It is hoped that the institution will form a rallying ground for members of the engineering profession throughout the Plate, and doubtless the movements of the association will have a considerable interest for engineers in all parts of the world.

Islington (London).—A discussion arose at the meeting of the Vestry last week on the cost of public electric lighting. Mr. James thought the time had arrived when the electrical department should consider the question of reducing the cost of current for public lighting. The lamps cost £40 each per annum, which was in excess, he said, of the cost in any other metropolitan parish. Mr. Gordon, chairman of the Electric Lighting committee, said that as the whole question of price was about to be reconsidered, there would probably be a considerable reduction, and he denied that the price charged at Islington was greatly in excess of other parishes.

Kensington (London).—The Electric Lighting committee recommend the Vestry to apply for a provisional order.

Lectures.—A course of 28 lectures on "Elementary Metallurgy" will be given by Mr. W. J. Pope, at the Goldsmith's Institute, New Cross, S.E., on Wednesday evenings at 8.30. The fifth lecture will be given on Wednesday next, Nov. 2. The lectures will be illustrated by experiments, lantern slides, and diagrams.

Lewes.—The transfer of the Lewes provisional order is at present engaging the attention of a committee of the Town Council.

Light Railways.—The Light Railway Commissioners have sanctioned the application of the British Electric Traction Co. for powers to construct a light (electric) railway between Merthyr, Dowlais and Cefn.

The Middleton light (electric) railway scheme, recently sanctioned by the Light Railway Commissioners, came before Sir Courtenay Boyle and Sir Thomas Blomfield for confirmation last week. The promoters are the British Electric Traction Co., and the objectors were the Middleton, Oldham and Rochdale Corporations, who contended that the terms of purchase should be altered so as to approximate to those of the Tramways Act, 1870. In the order of the Light Railway Commissioners the projected lines cannot be bought out under 25 years, and then only on terms which are much less satisfactory from the point of view of the local authorities than those of the Tramways Act. Middleton, which is erecting an electric plant of its own, is desirous of supplying motive power to the new line, and Oldham, it was urged, ought not to be compelled to submit to a few hundreds of yards of line being put down within the borough. The decision of the Board of Trade was, however, reserved.

Digitized by Google

London County Council.—At Tuesday's meeting, it was agreed to lend the Islington Vestry £22,500 for use in extending the electricity supply works at Eden-grove. The Finance Committee reported that the Shoreditch Vestry had applied for a loan of £20,539 to defray the cost of the acquisition of land and for the installation of the electric light in the parish, and the committee recommended that £8,200 be granted, and further that the Vestry be notified "that, as they have elected to spread the whole of the initial cost of the proposed additions and extensions of the electric light installation over 42 years, the Council will decline to give its sanction to the raising of any loan to replace any of the plant and machinery which may be necessary during the currency of the loan, and will expect the Vestry to provide for all replacements and renewals required during that period out of a sinking fund to be provided for that purpose or from maintenance account." This report was, however, withdrawn at the request of the chairman of the committee.

Earl Russell has been appointed on the Highways Committee, in the place of Mr. Baker, resigned.

Lye (Stourbridge).—Mr. F. J. Warden-Stevens has been retained to advise the District Council as to the establishment of electricity supply works.

Malakand (India).—Lieut. C. O. Halliday, R.E., has been deputed to consider and report upon the question of establishing electricity supply works on this frontier station.

Malta.—The revenue from the electric light works for 1897 amounted to £9,122 against £346 in 1896. The municipal installation came into operation in Dec., 1896, and the takings in 1897 included £6,947 paid by the Government for street lighting.

Manchester.—Major-Gen. H. D. Crozier held an inquiry on Monday into the application of the City Council to borrow £200,000 for electric light extension purposes. The deputy town clerk (Mr. Hudson) said that the electrical undertaking had been in existence a little over five years. At the present time there was an equivalent of 214,946 8 c.p. lamps connected, and 31,760 lamps waiting to be connected, which they would not be able to connect until plant, which had been authorised by the Local Government Board, and was now being constructed, had come into operation. The charges for electric current were 5d. per unit, or for large consumers 1½d. per unit, and £7 per annum per kilowatt. The Electricity committee had, up to March last, placed to reserve and renewal funds £34,245, and had handed over to the city fund £26,694, making £60,939, which for the period over which it extended was equal to a rate of rather more than a penny in the pound. This success had not resulted in any damage to the gas undertaking, which also belonged to the Corporation. In regard to water and gas supply and other matters there was a community of interest between the city and the surrounding urban districts, and there was a demand that Manchester should supply those districts with current for lighting and also for tram traction. The Corporation obtained parliamentary power in 1897 to meet that demand. In the same session several of the surrounding urban districts applied to the Board of Trade for and obtained provisional orders for supplying the districts with electricity. These districts were Denton, Droylsden, Levenshulme, Moss Side, Stretford and Withington, and all these orders were confirmed by one act. Failsworth, Heaton Norris, Gorton and Audenshaw were now seeking similar powers. The Manchester Corporation had made definite arrangements for supplying electric current to Levenshulme, Moss Side, Withington and Heaton Norris, but as the latter district had not yet got its order it was not possible to take action so far as that township was concerned. The main purpose of the present application had reference to the supply of electricity to Levenshulme, Moss Side and Withington. Negotiations were also pending in respect of other districts, and there was every probability that several of these would want to be supplied by Manchester. The price charged for current in the outside districts would be the same as in the city. The sum now sought to be borrowed was required for works that would be necessary to meet present and prospective demands. It was estimated that £116,558 would be required within the city, £52,332 in the Withington district, £16,002 in Moss side, and £9,400 in Levenshulme. The electrical engineer (Mr. C. H. Wordingham) had set aside a sum of £5,708 for contingencies. Of the £200,000 £7,000 was required for land, and they asked that the repayment of that should be extended over 50 years, and the remainder of the sum to be repaid in 25 years, the term granted in respect of previous applications. Mr. Alderman Lloyd Higginbottom, chairman of the Electricity committee, said that current was first supplied in July, 1893, and they had had extreme difficulty in meeting the demand for electric light and power within the city. Large extensions of plant had been made during the past two or three years, and the demand continued so great that further extensions were absolutely necessary. It was partly to meet these demands that the present borrowing powers were required. In accordance with the terms of the agreements entered into with Moss Side, Levenshulme and Withington, the compulsory streets mentioned in their orders had to be lighted by the Manchester Corporation within two years from Aug. 6, 1897, and, therefore, the necessary feeder and distributing mains and transformer stations should be at once proceeded with in these districts. The Council had instructed the committee to light up a large number of the principal thoroughfares in the city with arc lamps, if possible, during this winter. The expenditure on this item would be £11,500, and this was included in the application. The posts carrying the arc lamps would be about 43yds. apart, placed alternately on opposite sides of the streets. The Corporation, having obtained powers to work the tramways by electricity, had decided that these tramways should be equipped and ready for running in April, 1901, and it was probable that the overhead system of traction would be employed. The posts carrying the arc lamps would be prepared to receive the cross-span trolley wires for the tramcars, so that the work would not have to be done twice over. The provision of the transforming stations and transformers, for which borrowing powers were now sought, would also be applicable for the supply of electricity for the working of the tramcars. The capital expenditure incurred to the close of the financial year to March 31 last was £357,617. When the new 100 H.P. generator, now in course of erection, was completed there would be provision for 220,000 8 c.p. lamps. The following figures showed the extent to which the demand for the current had increased :—

	No. of consumers.	Equivalent 8 c.p. lamps.
December, 1893	289	32,716
December, 1894	624	60,298
December, 1895	1,016	93,290
December, 1896	1,466	133,504
December, 1897	1,869	171,396
October 20, 1898	2,281	214,946

When applicants now waiting for connection had been dealt with the total number of consumers would be 2,411, and the number of equivalent 8 c.p. lamps 246,706. It had been agreed by the committee to recommend the Council to abolish meter rents as from March next. The borough electrical engineer (Mr. C. H. Wordingham) gave full technical details of the propcsed extensions, and the inquiry closed.

At the special meeting of the City Council on Wednesday, the resolution referred to in our issue of Sept. 30, giving notice to the Manchester Carriage and Tramways Co., that the Council propose to acquire by purchase the undertaking of the company, was passed.

Marylebone (London).—Last evening the report of the Electric Lighting committee recommending "That the committee be empowered to enter into preliminary negotiations with the Metropolitan Electric Supply Co. for the purchase of their undertaking in this parish and to report to the Vestry" was discussed. Mr. Brooke Hitching, chairman of the committee, moved the adoption of this report, and said it was a recommendation upon which the committee were unanimously agreed. It was very desirable that the electric light monopoly should be broken, and the committee had done all it could to break that monopoly. The money they had spent in endeavouring to obtain a provisional order had not been lost, for they had wrung concessions from the Metropolitan Company that more than paid the ratepayers. The committee asked for the fight to be continued. Should they be unable to obtain powers for electric lighting, then they could do what other parishes had done, and buy out the company. He maintained that it would be to their advantage to purchase the company's undertaking. Mr. T.W. Baker seconded. Sir Edwin Galsworthy said he thought that Mr. Brooke Hitching was wrong in stating that concessions had been wrung from the company, because he saw that other parishes were to have similar concessions. He would ask the Vestry to mind what they were doing in giving the committee the powers they asked, or they would be landed into a great expense. He questioned whether this Vestry had the power to purchase the company's undertaking, or whether the company could sell to the Vestry. He moved an amendment that the committee be empowered to ascertain if the company is prepared to sell the whole or part of its undertaking to the Vestry, and, if so, on what terms. Mr. E. White seconded. Mr. Brooke Hitching said he hoped the Vestry would not delay. In regard to the powers of the Vestry to purchase, the Board of Trade reserved to itself the power of transferring on terms to vestries. The amendment was declared lost. Mr. Stringer moved another amendment that the question be postponed. Mr. Chick seconded, and said that no person who had a pecuniary interest in the company they were to negotiate with should be on the committee. Mr. Anglin said he would urge Mr. Brooke Hitching either to withdraw from the committee or sell out his shares in the company. Mr. Brooke Hitching said he had disposed of his shares in the company. The amendment was lost, and the committee's recommendation was agreed to.

Motherwell.—The Town Council have adopted the recommendation of Prof. A. B. W. Kennedy to establish electricity supply works at a cost of about £23,000. Current is to be supplied for both public and private lighting. The street lighting is to be effected by 30 arcs and 400 32 c.p. incandescents.

Digitized by Google

Oldham.—The Town Council have resolved to promote a bill for powers to work the Oldham tramways and also the lines belonging to Royton, Crompton and Lees, and to adopt electric traction on the entire system.

Pembroke (Dublin).—The Town Council have fixed the charges for current for private lighting at 6d., and for power at 3d. per unit.

Provisional Order Notices.—The Corporations of Ludlow and Kidderminster give official notice of their intention to apply for provisional electric lighting orders.

Queenstown (Cork).—In the *Dublin Gazette* of the 18th, notice is given that the Township Commissioners have transferred their provisional order to the Cork Electric Tramways and Lighting Co. The Commissioners retain the right of purchase.

Rontgen Rays in War.—The ambulance section of the V.B. Royal Warwick regiment lately gave an interesting demonstration of Röntgen ray field practice recently at Ward End, Birmingham. A kind of field hospital was formed, and imaginary patients were manufactured. Bullet and bayonet wounds were assumed, and it was in connection with the former that the Röntgen ray demonstration was particularly successful. A complete portable set of apparatus was supplied by Henry W. Cox (Limited), and this was carried by four men upon a stretcher. Following this came two men, each carrying an accumulator. Two other men had charge of a collapsible developing tent, and the rear was brought up by two men with a box containing photographic films and chemicals for 150 exposures. Bullets were assumed to have struck various parts of the bodies of the "patients," and successful demonstration was made of the efficiency of the apparatus. It was agreed by those who took part in the performance that the application of Röntgen rays to military service had been demonstrated to be of great usefulness.

Runcorn.—Consistency is not the characteristic of the members of the Electric Lighting committee of this town. Some time ago it was decided to apply for a provisional order, but subsequently it was thought that the cost of obtaining the order was too great, and negotiations were opened up with a company which had given notice of its intention to apply for electric lighting powers. The committee have now reverted to the original proposal to themselves apply for an order.

Smoke Nuisance.—The Metropolitan Electric Supply Co. were summoned at Marylebone (London) on Friday by the Paddington Vestry for allowing dense black smoke to issue from the shaft at their Amberley-road station in such quantities as to be a nuisance. After a lengthy hearing Mr. Curtis Bennett inflicted a fine of £5 with £10. 10s. costs.

St. Annes (Lancs.).—This Council is in possession of a provisional order, and the Electric Lighting committee is considering the advisability of carrying out its terms. Three courses have been suggested: (1) To make arrangements with the Corporation of Blackpool to extend their mains to the district; (2) to transfer the order to a company; and (3) to put down an independent installation. It has, however, been decided to first of all consult an engineer.

Stourbridge.—The District Council have decided to apply for a provisional order, and a special committee has been formed to promote the application, with power to engage a consultant.

Telephone Municipalisation.—A deputation from the Manchester City Council, consisting of Alderman Southern, Mr. Brocklehurst, Mr. Copeland and the town clerk (Mr. W. H. Talbot), waited upon the Postmaster-General yesterday (Thursday) to discuss the present condition of the telephone service in Manchester.

At a meeting of the City of London Common Council last week it was resolved to urge upon the Government the extreme desirability of action being taken forthwith to give effect to the recommendations of the House of Commons committee on the telephone service.

The Lord Provost's committee, Edinburgh, has been instructed to report upon the question of obtaining powers to establish a telephone exchange.

The Telephone Users' Association, of Norwich, have sent the following note to the Press:—

"It is evident, from the fact that licences have been granted to Glasgow and Huddersfield, that the Government do not intend to take over the telephones, but to grant licences to municipalities, or to companies under their control, in accordance with the terms of the Treasury Minute of May, 1892. This will entail upon every Corporation anxious to have the control of the telephone exchange the trouble and inconvenience of obtaining a special act of Parliament for its own particular locality. What is wanted now is pressure to be brought upon the Government to bring in a general enabling act, whereby municipalities will be able to immediately take up the telephone business and work it in suitable areas, the extent of which ought to be at once under the consideration of every municipal authority. The chief point that requires the consideration of each town is, what extent of area suits the surrounding neighbourhood."

Telegraph Money Orders to Germany.—The Postmaster-General notifies that on Nov. 1 the telegraph money order system will be extended to Germany. No single order can be issued for more than £10. The sender of an order will be allowed, on paying for the additional words, to add to the official telegram of advice any short communication he may wish to send to the payee.

Wallasey.—In the Improvements bill which the District Council have decided to promote, power is sought to purchase and work the local tramways, and to introduce electric traction.

Weston-super-Mare.—The Lighting committee have practically arrived at an understanding with the Electrical Power Distribution Co. for leasing their provisional order for ten years, after which time the Council can acquire the undertaking on a valuation at twelve months' notice. The Company undertake to lay mains in the whole of the compulsory area and along the sea front within twelve months of the signing of the agreement. For private lighting the charge for current will be 8d. per unit for the first hour and 2d. afterwards, and for public lighting the price will be about 2½d. per unit.

Willesden.—The District Council decided at their last meeting to oppose the application of the Metropolitan Electric Supply Co. for a provisional order. The newly appointed electrical engineer (Mr. E. T. Ruthven Murray) will not be able to take up his duties before the end of December, but in the meantime the committee having charge of electric lighting matters is endeavouring to acquire a site for electricity supply works. The Council have also sent out circulars to builders pointing out the advisability of wiring new houses.

Workhouse Lighting.—The Croydon Guardians have authorised their Electric Lighting committee to consult an electrical engineer as to adopting electric lighting at the workhouse and institutions under the guardians' control.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

13,399. Déri. Method of combined application of continuous and alternating currents for exciting magnetic fields and combination apparatus for producing by this method electrical energy and mechanical power.
14,090. Royce and Claremont. Means of lowering the load of cranes or hoists driven by electromotors.
14,732. Déri. Method for obtaining combined alternating and continuous currents and distributing the same for the electrical transmission of power, particularly for electrical traction.
15,222. Lake (Burns). Electric accumulators.
16,155. English Industrials (Limited) and Heyl-Dia. Globes of electric incandescent and similar lamps and lamp shades or chimneys.
16,875. Schattner. Electricity meters.
17,280. Bergmann. Electrically driven fans or ventilating devices.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia and China Telegraph Co. (Limited).

The fiftieth half-yearly ordinary general meeting of this Company was held on Wednesday, the 26th inst., at Winchester House, Old Broad-street, London, the Most Hon. the Marquis of Tweeddale, K.T., presiding.

The MANAGER and SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting, together with the minutes of the forty-ninth half-yearly ordinary general meeting, which were confirmed and signed by the Chairman.

The CHAIRMAN: Gentlemen, before asking you to approve of the motion—

"*That the report and accounts of the directors, now submitted, be received and adopted,*"

I will trouble you with a few observations on the proceedings of the half-year which ended last June. The gross revenue for that period amounted to £277,282, being a decrease of £13,467 as compared with that for the corresponding period of 1897. This will not be regarded, I think, as unsatisfactory when it is borne in mind that the past half-year compares with a period when the China, Japan, and other tariffs were considerably higher and that the political disturbances and cutting of our cables between Hong Kong and Manila and Manila and Panay seriously affected our traffic with the Philippines. From these causes a much larger decrease might have been anticipated, but happily the growth of traffic in other directions has very nearly made up the deficiency (hear, hear). The working and other expenses have amounted to £102,873, being an increase as compared with those for the corresponding period of 1897 of £3,448, which is accounted for by the repairs to cables having been heavier during the past half-year than in the same period of 1897, and also by the opening of the several stations in the Philippine Islands, under an arrangement with the Spanish Government, which was reported at length at our last meeting. The usual interim dividends at the rate of 5 per cent. per annum have been paid for the past half-year, amounting to £62,500, and after transferring £50,000 to the general reserve fund, the sum of £10,723 is carried forward to the next account. During the half-year under review the policy of strengthening the weak portions of the Company's system has been steadily pursued, with the result that the Penang-Sumatra cable has been entirely renewed, the Java-Port Darwin duplicate cable has been renewed to the extent of 135 nautical miles, and 207 nautical miles have been added to the Hong Kong-Manila cable. The cost of this work has been £46,709, the whole of which, as you will have, no doubt, observed from the accounts, has been debited to the general reserve fund. When I last had the pleasure of addressing you, I referred to the dangers and privations to which our staff was exposed in the Philippine Islands, owing, in the first instance, to the native rebellion, and afterwards to the hostilities which broke out between Spain and the United States. This latter event rendered the position of our staff, as you may easily imagine, a very delicate one, and this dangerous condition of things lasted for several months; but I am happy to say that although much damage was done to the property, both public and private, connected with our establishments there, no lives were lost, and I do not think that any personal injury was sustained beyond the great privation which was suffered by our employés. When the peace preliminaries were concluded we were able to make a very satisfactory arrangement with the two Governments under which both the Hong Kong-Manila and the Manila-Panay cables were reopened on a neutral basis, so that the Company are now working at Manila direct with the public, instead of through the medium of the Spanish officials, as heretofore. (Hear, hear.) Unfortunately, the political situation is still unsettled, and further fighting was reported a few days ago in the neighbourhood of our Tuburan station, in the island of Cebu. I may mention that the courage and devotion to duty displayed by the Company's staff during the earlier troubles at Cape Bolinao have been specially recognised by the Spanish Government by the granting of suitable decorations to the officers concerned (cheers); and I cannot myself personally refrain from expressing my admiration of the conduct of Mr. Herbert Jones, our superintendent, and his subordinates during the extremely trying times through which they have passed (applause). The time will, I hope, come when we shall be able to recognise from this side of the table the services they have rendered during this period (hear, hear). The Company's claim against the Government of the United States of America for compensation in respect of the loss and damage sustained through the cutting of the Manila cables has not yet been admitted, and the Government appears to be under the impression that the repair of the Hong Kong cable was effected by their own officials. This, however, was not the case, as the repair was temporarily made by the Company's staff with the assistance of an American tug boat, but it was permanently effected within a few days afterwards by our own steamer, the "Recorder." I have on more than one occasion referred to the probability of the establishment of cable communication in the Pacific. The occupation of the Philippines by the United States has undoubtedly given a stimulus to efforts having this object in view. As far, however, as we know, nothing definite has yet been arranged, and all I can say with respect to this matter is that we are carefully watching developments in that direction, and I think you may rely upon it that we are taking steps to protect your interests in every possible way (applause). With these observations I beg to ask you to adopt the report and accounts now submitted.

Mr. FRANCIS AUGUSTUS BEVAN seconded the resolution, which was carried unanimously.

Mr. JOHN NEWTON afterwards proposed a vote of thanks to the chairman and directors, and remarked that the way in which the Company had been managed in the past should give the shareholders confidence with reference to the future.

A SHAREHOLDER seconded the motion, which was carried unanimously.

The CHAIRMAN acknowledged the vote and the proceedings then terminated.

Brazilian Submarine Telegraph Co. (Limited).

The fiftieth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, London, on Wednesday, under the presidency of Mr. J. Denison Pender.

The SECRETARY (Mr. E. Steer Hodson) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said: Gentlemen, the income for the half-year ended June 30, 1898, amounted to £103,689; for the previous half-year it was £100,300, showing an increase of £3,389 resulting from the following increases:—£1,964 in message receipts, £1,420 in dividends onshares in other telegraph companies, and the small sum of £5 from bank interest, &c. Taking the expenditure side of the account, we find that the total expenditure for the half-year is £21,474, and that for the previous half-year was £26,166. There is, therefore, a decrease of £4,692; but this decrease, as I have often explained to you,

Digitized by Google

gentlemen, is entirely a question of repairs or no repairs to cables. In the previous half-year there was a sum of £5,725 spent on repairs of cables, but in the half-year ended June last we were fortunately free from any such expense. Increases are apparent in the following expenditures:—In London of £351 and at stations of £834, making a total of £1,185, but there is a small decrease under other items amounting to £152. Therefore a net increase is left of £1,033, which, deducted from the £5,725 I have referred to, leaves the net decrease in the half-year £4,692, as I have previously mentioned. I have before me the details of the increases and decreases, but I think I need not go further into them unless you wish it. After payment of £3,200 for debenture interest and sinking fund, and providing for the payment of income tax, there is a credit balance on the half-year's business of £77,301. To this is added £8,662, the balance brought forward from December 31st, making together £85,963. The usual interim dividend for the March quarter, amounting to £19,500, has been paid, and £25,000 transferred to the reserve fund. The directors now recommend the declaration of a final dividend of 3s. per share making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share, both free of income tax, which together will amount to £32,500, leaving a balance of £8,963 to be carried forward. With respect to the condition of the cables, the Lisbon-Madeira No. 1 cable previously referred to as faulty continues to work satisfactorily, therefore no attempt to remove the fault will be made so long as the cable performs its work. The Madeira-St. Vincent No. 2 cable is falling in capacity, and it seems probable that at an early date steps will have to be taken to have the fault removed. That will be an expensive matter, because the cable is lying in deep water—very likely, considerably over 2,000 fathoms; and although we constantly see in the papers that these depths can be easily dealt with and the cables easily handled, our experience is that, although they can be repaired as a certainty, it is very often a very long and costly job to do. Gentlemen, this deals really with the Brazilian Submarine Company's accounts as the Brazilian Submarine Company pure and simple for the last time, because next half-year we shall also be taking into consideration the results of the working of the Western and Brazilian Company, in conformity with the arrangement which has been carried out. Therefore what I have said deals with the past, and I will now just say a few words on what has taken place since we last met. You will remember that the last meeting we had was in August—August 11th—for confirming the carrying out of the arrangement entered into with the Western and Brazilian Company. The Western and Brazilian shareholders have sent in their assents to a very much larger amount than was required for the legal majority to carry the arrangement which was entered into by the two Boards; and the result is, gentlemen, you now see, I am glad to say, sitting on the Board of the Brazilian Submarine Co. the directors of the Western and Brazilian Co., Mr. Andrews, Lord Richard H. Browne, Mr. Coppen and Mr. Goodsall, whom I have the pleasure of introducing to you. I may also say, personally, that I am taking the chair here for the last time. The Board considered—and very rightly, too—that Mr. Andrews, who has been for very many years associated with the telegraph world, being the chairman of the Western and Brazilian Co., and very closely associated with the Indo-European Co.—they considered that his seniority as a telegraph director entitled him to take the chair of the joint Board; and I need hardly say that I myself most thoroughly concur with the rest of the directors in that opinion. There is also another reason why it will certainly be to the advantage of the Company that Mr. Andrews should be chairman. Mr. Andrews, as presiding over the Western and Brazilian Co., has naturally had a good deal of intercourse with the Brazilian Government. The cables of the Western Company are laid along the shores of that country, and call in at many of the ports, whereas we only run to Pernambuco. In the arrangement entered into between the two Boards it is very natural that the Brazilian Government might consider, without knowing the facts, that the combination might be disadvantageous to themselves and the public, and, after all, it is their duty to see to such a matter. They might think that it was a combination for the raising of the rates, but I am perfectly certain that directly they see that the gentleman who has been Chairman of the Company closely associated with them has become Chairman of the joint Board, any suspicion—if I may use that word—if there is any, will at once be allayed. I ask you to support Mr. Andrews as Chairman of this Company in the same way that you have always supported whoever has presided at these meetings—a fact which has rendered our meetings a pleasure for the Board to attend and meet the shareholders. Now, with respect to the staff, of course, in the arrangements which have had to be made between the two Companies, the old servants who have grown up in the employment of both, have had to be taken into consideration, and into careful consideration; but the appointments which affect you, the shareholders, perhaps more than any others, are those of the Manager and Secretary. You see in the report that Mr. Axworthy, who has been here since the Brazilian Submarine Company first commenced business, as traffic accountant and general accountant, has been appointed Manager, and it is with very great pleasure that the Directors have placed him in that position. On the other hand, Mr. Hodson, who has been brought up in a very good school (he began in the Eastern, then went to the Brazilian Submarine, and then to the Western and Brazilian, and has spent the whole of his commercial life in the telegraph service), has been appointed, I am glad to say, Secretary to the Company. But in carrying out these arrangements, especially with the Secretary, there is one name which all those shareholders who have watched the progress and have read the reports of the Brazilian Submarine Company will notice as being omitted from the outside sheet of our report on this occasion—I refer to the late Secretary, Mr. Collett. Mr. Collett has been for nearly 26 years the Secretary of the Brazilian Submarine Company, and he has been anxious to retire for the last two or three years. By the directors' desire, however, he remained with the Company to see what would become of the negotiations which were then on the *tapis*, and which since then have been so successfully carried through. Directly that took place Mr. Collett retired from the secretaryship of the Company, and I am sure that there is not a shareholder in the Company who will not endorse the action of the directors in giving Mr. Collett, as they have done, a pension of £500 a year for his honourable and most faithful service to the Company during 26 years. Now I think I have given you a good deal of detail, and you must not forget that this is the fourth meeting we have held during the last six months. The first one was the usual half-yearly meeting; the second was the meeting at which the agreements were brought forward; the third was the meeting to confirm those agreements, and make them legal; and the fourth we are present at to-day. I therefore think that the shareholders and directors who have attended these meetings have at any rate done their duty towards the Company. I will now propose the resolution, but will anyone who has any question to put, or who wishes for further information, ask me now? After a pause, and no shareholder rising to address the meeting, he continued: Gentlemen, there appear to be no questions to ask, and I will therefore now move the following resolution:—

"*That the report of the directors and the accounts to June 30, 1898, now submitted, be approved and adopted, and that a dividend be now declared of 3s. a share, making with the interim dividends already paid a total dividend of 6 per cent. for the year, and also a bonus of 2s. a share, making in the aggregate a distribution of 7 per cent. in respect of the profits for the year ended June 30, 1898, the said dividend and bonus to be respectively free of income tax.*"

Mr. FREDERICK YOULE seconded the motion, which was carried unanimously.

The retiring auditors were afterwards re-elected.

The Rev. WILLIAM HICKMAN then proposed a vote of thanks to the chairman and directors for their able and efficient management in the past six months.

Mr. CHARLES H. HOBBS seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, and the proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRO-SMELTING CO. (LIMITED).—This company was registered on Oct. 22, with a capital of £10,000, in £50 shares, to acquire, sell, dispose of and deal with mines, minerals, mining rights, &c., and to win, reduce and refine ore and mineral substances and precious stones.

GENERAL WATER POWER (LIMITED).—This company was registered on Oct. 22 with a capital of £21,500, in £1 shares (of which 1,500 are Deferred), to produce electricity by means of water power or otherwise, and to carry on the business of electricians and suppliers of electricity. The first subscribers, with one share each, are: P. H. Sainsbury, P. G. Tovey, C. Boyle, H. P. Cousins, C. F. A. Spashett, J. H. McCashen and P. H. Hetherington. The first directors are: Montagu F. Armstrong, John S. Bergheim and the Hon. William Vernon.

NATIONAL CONDUIT AND CABLE CO. (LIMITED).—This company was registered on Oct. 21 with a capital of £1,000, in £1 shares, to construct, lay down, fix and complete, any conduits, cables, wires, lines, accumulators, and works in connection with electric telegraphs, telephones, electric lighting, &c., and to carry on the business of manufacturers of cables and wires for electrical purposes, electrical engineers and contractors, suppliers of electricity, manufacturers of electrical apparatus, &c. The first subscribers (each with one share) are: C. T. C. Price, H. G. Carvall, N. G. Newington, G. J. Jackson, C. W. Barrett, J. H. Bodell and A. Benwell.

TELEPHONIC BELL PUSH SYNDICATE (LIMITED).—This company was registered on Oct. 20 with a capital of £2,000, in £1 shares, to acquire, develop, work and deal with an invention for improvements in telephonic bell pushes, and to enter into an agreement with G. L. Anders and A. J. Wilson, jun. The first subscribers (each with five shares) are: A. J. Wilson, jun., G. L. Anders (electrician), F. M. Robertson, J. King, J. F. Jamieson, L. W. Stanley and F. O. Jerram.

SUNBEAM LAMP CO. (LIMITED).—The annual return to Aug. 19 has been filed. The capital is £25,000, in £10 shares, of which 1,765 shares have been taken up. 857 have been issued as fully paid, and the full amount has been called and paid on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). **Price of silver** 27$\frac{1}{16}$d. **per oz.** (Oct. 27). **Consols** (2$\frac{3}{4}$ **per cent.**) 108$\frac{7}{8}$—109$\frac{1}{8}$ **for money,** 108$\frac{7}{8}$—109$\frac{1}{8}$ **for account; 2$\frac{1}{2}$ per cent.** 103$\frac{1}{2}$—104 (Oct. 27). **Stock Exchange Settling Days: Consols, Nov. 4; Stocks and Shares Continuation Days,** Nov. 9 and 28; **Ticket Days,** Nov. 10 and 29; **Pay Days,** Nov. 11 and 30; **Mining Share Carry-over Days,** Nov. 8 and 26.

AKKUMULATOREN FABRIK AKTIEN-GESELLSCHAFT (BERLIN).—This company has declared a dividend of 10 per cent. for the past year (same rate as in 1896-97).

BARROW-IN-FURNESS TRAMWAYS CO. (LIMITED).—A provisional agreement has been entered into for the sale of this company's under

Digitized by Google

taking to the British Electric Traction Co. (Limited), at £22,750, the Corporation of Barrow having, however, the right of refusal to buy at the same price.

CALLENDER'S CABLE AND CONSTRUCTION CO. (LIMITED).—The directors of this company have declared an interim dividend of 5s. on the Ordinary shares (at the rate of 10 per cent. per annum).

CITY OF LONDON ELECTRIC LIGHTING CO. (LIMITED).—The revenue return of this company for supply of electricity only for the quarter ended Sept. 30 is as follows: Gross revenue from sale of current for public lighting £3,196, against £3,146 in the corresponding period of last year; private lighting, &c. (less allowances to customers) £23,705, compared with £21,978; making a total of £26,901, against £25,124, an increase of £1,777. On Sept. 28 there was an equivalent of 334,573 8-c.p. lamps connected, being an increase of 12,873 during the quarter, against an increase of 7,264 in the corresponding quarter of 1897. In the corresponding quarter last year the charges were under the old scale.

FORT WILLIAM ELECTRIC LIGHTING CO. (LIMITED).—A meeting of this company was held recently at Fort William, when the directors recommended a dividend of 2½ per cent. for the year from April 30, 1897, on the original capital of £7,000, and a like dividend on the increased capital of £2,000 from Feb. 1. A balance (£110. 17s.) was carried forward. The managing director (Mr. R. F. Yorke) stated that the plant and mains were in good condition; the number of consumers had considerably increased; the result of the past 18 months' work was considered satisfactory, and better results were anticipated.

MONTEVIDEO TELEPHONE CO. (LIMITED).—The report of the directors of this company for the year ended July 31 states that the accounts show a net profit for the period of £6,827, after providing for all working expenses in Montevideo and London, and writing off amounts for bad debts, depreciation of stock of materials at Montevideo and office furniture. £976 is brought forward, leaving an available balance of £7,803. The value of subscriptions has continued to increase. The expense of removals and repairs of instruments has been considerable during the past year, which accounts for an increase in working expenses at Montevideo. The plant has been kept in efficient repair at the cost of revenue. The directors recommend the payment of the full 5 per cent. on the Preference share capital, absorbing £4,200, and leaving, after placing £1,000 to reserve fund, the sum of £2,603 to be carried forward, sufficient to provide for a dividend upon the Ordinary shares after the promissory notes have been cancelled.

NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).—The petition to further reduce the capital of this company, which was before the Courts last sittings, has been restored to the list for hearing on next petition day.

NORTH STAFFORDSHIRE TRAMWAYS CO. (LIMITED).—At a meeting of this Company last week, the Chairman (Ald. E. J. Hammersley, J.P.) said that the negotiations with the British Electric Traction Co. for the purchase of their undertaking would be completed in a few days. He was informed that a new company had been registered, and was in process of flotation, for amalgamating the powers which the North Staffordshire Tramways Co. possess, and the powers obtained by the Potteries Extension Co.

ORIENTAL TELEPHONE AND ELECTRIC CO. (LIMITED).—An interim dividend of 4d. per share, free of income-tax, is declared.

STOCK EXCHANGE NOTICE.—The Stock Exchange Committee has ordered the further issue of 7,500 £5 fully paid Ordinary shares (Nos. 22,501 to 30,000) and 7,500 £5 fully paid Six per Cent. Cumulative Preference shares (Nos. 52,501 to 60,000) of Willans and Robinson (Limited) to be quoted in the Official List. The Committee has also been requested to allow the £4,000,000 Ordinary stock of the Eastern Telegraph Co. (Limited) to be quoted in the Official List in lieu of the Ordinary shares now quoted.

TELEGRAPH TO DAWSON CITY.—Mr. J. M. Catton writes to a contemporary that he holds a charter, which received the Royal assent in June last, intituled "An Act to Incorporate the Dawson City and Victoria Telegraph Company." The charter confers the right to lay cable lines from Victoria and to complete the telegraph to Dawson City by land lines. The authorised capital, including debentures, is £525,000, and estimates for construction have already been passed, and the work will be taken in hand and construction commenced immediately.

UNION ELEKTRICITATS GESELLSCHAFT (BERLIN).—At the forthcoming meeting the shareholders will be asked to sanction a proposal to increase the capital from 3 million to 18 million marks (£150,000 to £900,000). The new shares have been entirely taken up by the Ludwig Loewe Co. at 110 per cent. This company offers £150,000 to the old shareholders of the Union Company at 110, and £375,000 to its own shareholders at 135 per cent. The remaining £225,000 will be kept by the Loewe Company, which then will have an interest in the Union Company to the extent of about £275,000.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Oct. 21 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £3,404.

WIRELESS TELEGRAPH AND SIGNAL CO. (LIMITED).—An extraordinary general meeting of this company was held at the offices, 28, Mark-lane, London, E.C., on Monday, under the presidency of Mr. H. Jameson Davis, to confirm the resolutions passed at the meeting on the 7th inst., for increasing the capital of the company to £200,000 and for amending the articles of association by giving one vote for every share held, no member to be "entitled to vote in respect of any shares held by him in excess of two-fifths of the issued capital for the time being of the company." The chairman proposed the resolutions, both of which were carried. The chairman, in answer to Mr. Ashton, stated that the offer of the 25,000 new shares would be made to the shareholders who were on the register on Nov. 15. No fractions would be issued. Any shareholder who had odd numbers of shares, and was not entitled to a full complement of the new shares, must buy other shares, or if he had one or two too many, he must sell them. They had been advised that they could not deal in fractions.

NOTES.

FROM the POSTMASTER-GENERAL'S reply to a deputation of the Manchester Corporation on Monday, it appears that the next move towards the settlement of the telephone question will be to take the opinion of the House of Commons on the subject of the Select Committee's report. By the time the law has been amended so as to enable local authorities to erect public telephone exchanges it is doubtful whether many will find it worth while to avail themselves of the opportunity. Ratepayers who favour telephone competition in the abstract may yet oppose the borrowing of money for such an undertaking when they realise that the sum would have to be redeemed in twelve years' time. It is significant that the Manchester Corporation want to make a cat's-paw of the New Mutual Telephone Co., in the same way as the Select Committee suggest that local authorities may serve as a cat's-paw of the Post Office.

THE article, entitled "Telephones and the State," which will be found in another part of our present issue, is intended to assist the general reader in some measure to form a correct opinion of the recent Parliamentary Committee's proceedings, and to estimate the true value of its recommendations. In view of the changes of policy, and even of administration, which the report seems to foreshadow, this matter is of some considerable importance just now.

WE publish this week an abstract of the Report of the Permanent Committee on Terrestrial Magnetism and Atmospheric Electricity to the International Meteorological Conference, a document which, although principally framed in the interests of an important branch of pure science, is not devoid of interest for practical engineers. The proceedings of the International Magnetic Conference during the British Association week, at Bristol, have been duly notified in our columns, and a list of the Papers read appeared in *The Electrician*, Vol. XLI., p. 686. In the abstract we give of the Report there is evidence that the Conference was made use of by the permanent committee of experts to frame a valuable set of recommendations to the International Meteorological Conference.

SUCH of these recommendations as relate to purely scientific matters call for little comment. They have regard to the equipment and working of magnetic observatories, to the best designs of instruments for the purposes of observation and research, and to the desirability of extending the field of observation by the establishment of new observatories in various parts of the globe. With the scientific motive for these recommendations we are in entire sympathy; and it is to be hoped that no commercial consideration will be permitted to prejudice the just rights of a branch of physical science, the full importance of which to posterity cannot be foreseen at the present time.

SEVERAL recommendations embodied in the report bear upon the disturbance of the work of magnetic observatories arising from electric tramways and other electric plant. It is evident that no observatory can of itself be shielded from such disturbance, since it is the essential business of the observatory to detect and record identically the same phenomena as are produced, on an exaggerated scale, by the electric traction plant. The remedy, if it is to be carried into effect, must be applied to the traction equipment, preventing it from affecting the normal terrestrial magnetic condition in the neighbourhood of the observatory. Appended to the report, as well as to our abstract, is the text of the clause introduced into the Bill authorising the construction of the electric tramway in the neighbourhood of Kew Observatory.

"WHY not gas trams?" asks an influential London newspaper, *apropos* of the proposal to adopt mechanical traction on the metropolitan tramways. *Why* gas trams?—is the obvious retort. Wherein has gas power shown its superiority over electric traction? Certainly not in point of numbers of lines, mileage of track, commercial success, or popular approval.

Digitized by Google

We do not deny that gas trams will work, after a fashion; nor even that in certain circumstances they can be made to pay; but in no respect can they be regarded seriously as a possible competitor of the electric car. On the continent, the gas interests have exploited one or two lines, not without a degree of success; and between Blackpool, Lytham and St. Anne's there runs a service of gas-driven cars, the performance of which affords an instructive contrast with that of the two electric tramways in and around Blackpool. We are content to let gas tramway traction have its full trial, fearing nothing as to the possibility of its staying the advance of electric traction throughout this country.

We publish two letters this week on the question of the breakdown at Brighton, chronicled in our last issue. One of these suggests as an explanation of the back current an interruption of the field circuit of the disabled machine causing a momentary increase of E.M.F. in that machine. We believe there is no reason to expect that the shunt circuit of the machine was interrupted before the cut-outs acted; but, even if that had been the case, we cannot conceive that the consequent increase of E.M.F. due to self-induction would have been sufficient by itself to neutralise the thousands of amperes which were flowing from the remaining machines. Our other correspondent favours the explanation we offered, but objects to the temporary replacement of the minimum cut-outs by heavy excess cut-outs, and states that to tie up the former would not in this case have saved the station from shutting down. He prefers our other suggestions of separate excitation and non-return cut-outs. It has also been suggested to us in conversation that the defect lay in the minimum cut-outs themselves, and that the current through them never did diminish to a minimum, but we are not inclined to support this view, if only for the reason that all the apparatus acted simultaneously.

The Electrical Engineers, R.E. (Volunteers).—The enrolment of men into this corps has now begun again. The headquarters are open between 7 and 8 p.m. on Mondays and Thursdays.

German Safety Regulations.—The regulations issued by the Verband Deutscher Elektrotechniker, to ensure safety in high and low pressure electrical installations, have been officially recognised by the German Government.

Institution of Junior Engineers.—Arrangements have been made for the members of this Institution to visit the King William-street station of the City and South London Railway extension works on Saturday, November 12th, at 3 p.m.

Cable Interruptions.—	Date of Interruption.
Bissao—Bolama	Aug. 3, 1898
St. Louis and Noronha	Oct. 17, 1898
Gibraltar—Tangier	Oct. 18, 1898
Pernambuco—Ceara	Oct. 19, 1898

A New Cuban Land-Line.—Capt. Brady, of the United States Signal Service, has been ordered to begin the construction of an overland telegraph line from Guantanamo *viâ* Santiago de Cuba to Manzanillo, Cuba. The line is to be used principally for the transmission of Government despatches, although commercial messages will be accepted.

Some Amusing Errors.—Our contemporary, the *Revue Pratique d'Electricité*, makes a sad series of blunders in an article on the Bristol B.A. meeting. Sir *Henry* Crookes is stated, in his presidential address, to have affirmed that *M. Olivier Ladger* and not M. Branly was the inventor of the coherer. We are sure that Sir William Crookes never disputed the claim of Branly to his invention, nor did Dr. Oliver Lodge—if that is the gentleman to whom our contemporary wishes to allude. M. Olivier Ladger is twice mentioned in the article, however, and M. Mascart is persistently printed Massart. Dr. Rucker we are also informed is professor of physics at the University of London.

The Maritime Electrical Association.—A new electrical association, bearing this name, and formed by electrical engineers in the maritime provinces of Canada, held its first regular convention in Halifax, N.S., on September 27th last. After the president, Mr. F. A. Bowman, had delivered his address, a Paper was read by Mr. F. A. Hamilton on "Electric Gong Buoys." The Paper described a system of buoys, devised by the author, in which electric bells, placed on the buoys and connected by cable with the land, were constantly kept ringing. Mr. Hamilton read a letter from Mr. Preece approving of the system, but suggesting the use of alternating currents instead of springs in the bell mechanism.

Electrical Machinery in Prussia.—Some interesting statistics are published in the *Reichsanzeiger* of Sept. 30th. Up to the beginning of 1898 there were no less than 2,490 machines in Prussia used for driving dynamos, while 815 were partially used for that purpose. These are tabulated as follows:—

Uses.	No. of Machines.	Horse-power.
1. For lighting purposes	2,873	154,772
2. For driving motors	61	10,785
3. For other purposes	25	7,278
4. For several purposes at the same time—		
(a) For lighting and transmitting power	325	84,216
(b) For other purposes	21	1,675
Totals	3,305	258,725

These figures include all State and private undertakings in Prussia, with the exception of those under the War Office and Admiralty.

Electrical Supply in Paris.—*L'Industrie Electrique* publishes some interesting figures giving details of the capacities and lamp connections of the central stations supplying Paris with electric light and power. There are in all six companies and one small municipal network, and the following table gives totals for all the districts:—

Plant Capacity.	
Dynamos	24,396 k.w.
Accumulators	3,243 „
Lighting.	
Number of arc lamps	11,028
Number of incandescent lamps	701,524
Total number of lamps reduced to equivalent of 10 c.p.	922,603
Total power necessary	36,906 k.w.
Motors.	
Number of motors for lifts	753
Power required	2,141 k.w.
Number of motors for miscellaneous purposes	841
Power required	1,731 k.w.
Total power required for working motors	3,872 „
Heating.	
Number of apparatus	130
Power consumed	127 k.w.
Total power consumed	40,905 „

New Electric Supply Works at Folkestone.—Electric supply at Folkestone was "inaugurated" on Wednesday last, although the works have been supplying light to private consumers for some months past. The central station is now practically complete, however, and on Wednesday the public arc lamps were switched on for the first time. The works of the Folkestone Electricity Supply Co. are situated at a considerable distance from the town, and the three-wire system at 420 volts is employed, the arc lamps being connected across the outers in series of eight. At present the equivalent of about 9,000 8 c.p. lamps and 24 arcs are connected to the mains, there being 75 consumers. The capacity of the station is about 300 kilowatts. An amusing feature of the inauguration ceremony was that the directors of the local gas company had been invited. At the luncheon which followed, the toast of the electricity supply company was proposed by one of these gentlemen, who informed the guests, amid much laughter, that, if he had not withheld his casting vote in the Town Council on a particular occasion,

Digitized by Google

there would have been no need for the ceremony which had just taken place. We reserve a full description of the works for an early issue.

Dublin Sub-station Attendants not "Boys."—*Apropos* of the statement in our leading article last week that "at Dublin it has been found possible to leave the sub-stations in the charge of boys," Mr. E. Bolton, who describes himself as "one of the unfortunate boys in question," writes to protest that what we had mistaken for boys are really men; "their faces," he says, "belie them." As Mr. Bolton appears to think an injustice has been done, and as we are far from desirous of causing harm by our remarks on the subject, we give below the leading points in his letter:—

"In your leader on polyphase traction, special attention is drawn to the erroneous idea that boys are employed to take charge of the sub-stations in Dublin. As such is not the case it should be contradicted, as it is very unfair to those who are in charge of the sub-stations in question. The leader implies that the stations are so simple that even a boy can be left in charge; also it implies that they are, therefore, paid at a boy's rate of wages; neither, I can honestly say, are true. . . . A rotary converter or a motor generator may require but very little attention, but certainly not less than any other type of dynamo. However, until about seven or eight months ago there were in charge of the sub-stations two men of over 27 years of age and two of 20 years. The latter two, I presume, have been taken for boys, as probably their faces belie them. Since that time there has been one man of 23 and three of 21 years of age in charge of the stations. Being, as I imagine, one of the unfortunate boys in question, I write to protest at being called such, for reasons already given, and I hope you will not consider it mere vanity. I consider that being called a boy, or at least doing a boy's work, would prove to be a barrier to me bettering my position in the near future, as I should like to do."

Bennis Stoker at Belfast Electricity Works.—Some further particulars of the Bennis automatic stoker erected at Belfast may serve as an interesting supplement to our descriptive article recently. The stoker, as erected at the Belfast station, is of the new pattern, and comprises the machine stoker and a new self-cleaning compressed air furnace. This enables the consumption of coal per square foot of grate per hour to be varied at will in a few minutes from a few pounds to as much as 40lb. or 50lb. The results obtained over a series of tests which the makers have been carrying out during the last fortnight at the station have been most satisfactory, and are roughly as follows:—A test on Oct. 12, when the machine was pushed as hard as possible all the time, gave an average evaporation of 12,580lb. per hour, the maximum evaporation being 13,900lb. in one hour. On Oct. 18 a trial was made with Welsh coal on the "Bennis" stoker and compressed air furnace, giving the following results:—

Average evaporation per hour from temp. of feed 50°F. 7,257lb.
Water evaporated per pound of coal from and at 212°F. 11·59lb.

The machine, it may be stated, was shut down for a considerable period, for the steam produced would have been more than necessary for the load. The hand-firing trial made with the same coal, on October 14th, gave an hourly evaporation (average), from temperature of feed 54°F., of 7,025lb., and the water evaporated per pound of coal from and at 212°F. was 10·6lb.

The Manchester Corporation and the Telephones.—The Postmaster-General (the Duke of Norfolk) on Monday received a Deputation, representing the Manchester Corporation, who desired to lay before him the views of their city with reference to the administration of the local telephone service. Mr. Alderman Southern acted as spokesman for the deputation, and said that the Manchester City Council had decided to support the petition of the New Mutual Telephone Co. (Limited) for a licence. Over £80,000 of the company's capital had, it was said, been subscribed. The present action had been taken largely because the Corporation would have to obtain a special Act of Parliament to enable them to establish a Municipal system. On behalf of the Corporation, he asked (1) whether the Post Office was considering the advisability of establishing a competitive service; (2) whether a licence would be granted to the New Mutual Telephone Co., provided they entered into a contract not to sell their undertaking to anyone save the Manchester Corporation; and (3), in the event of a negative answer to questions (1) and (2), to what extent the Postmaster-General intended to give effect to the recommendations contained in the Select Committee's report, especially under the following heads:—(a) By introducing a public bill for enabling the Postmaster-General to grant provisional orders to enable the local authority to lay down and work telephones in its own district and the districts of other authorities within a specified area; (b) to enter into an agreement that the Post Office will purchase the land, buildings and plant of the new undertaking in 1911; (c) toassist the Corporation to obtain a suspension of the sinking fund and allow payment of interest out of capital for, say, three years, in order to avoid an undue burden upon the rates; (d) definition of area to be of sufficient extent and to embrace the large towns near Manchester. The Duke of Norfolk promised to send full written replies to the two questions. In the meantime he said that it had been definitely decided not to grant any further licences to private companies. At present he did not feel justified in saying anything as to the future policy which the Post Office proposed to adopt. The Report of the Select Committee on Telephones was presented too late in the recent session for any expression of opinion to be taken from the House, and until that had been done he did not wish to say anything which could be construed into even a quasi pledge.

Motor-Car Trials in Paris.—In the competition of motor-cars for heavy loads, which took place in Paris from October 6th to 12th, the electrically propelled cars did not gain any distinction. Of the four electric cars competing, only one went through all the six journeys precribed as tests. These journeys were, however, of such a nature as to be particularly trying to electrical automobiles, being on three routes—26, 29 and 41 miles long respectively—with one minute's rest after each kilometre traversed. It is intended, according to the *Engineer*, to choose a special route for the electric cars next year, to fulfil as much as possible the conditions of town and suburban goods transport. The Jenatzy van of the Compagnie Général des Transports Automobiles is of the same system as the cab which took part in the recent Paris trials, except that it has no change-speed gear. The gross weight was 4,500 kg., including 1,500 kg. of dead weight and four passengers. The batteries of Fulmen accumulators weigh 1,200 kg., and the inventor claims that with these the van can run 120 km. With a discharge of 28 to 30 amperes the vehicle ran 12 to 13 km. an hour on the level, and on the up grades the discharge was 70 amperes and the speed 7km. an hour. The average voltage was 82. The van accomplished all six routes without incident. The Société des Electromobiles presented a van upon the Bersey system with a battery of Fulmen accumulators. It completed five out of the six journeys. The Krieger van was not ready before Monday, so that it was only able to cover the three routes once. As with nearly all the French electric cars, the energy was stored in batteries of Fulmen accumulators. The weight of the vehicle was 2,500kg., including 600kg. of dead weight. On the A route the average rate of discharge was 24 amperes at 85 and 86 volts, and the consumption was 6 kilowatt hours. The carriage work of the Mildé-Mondos van is, says our contemporary, of the highest class description, and is fitted with a duplex motor, the power being transmitted by chain from a very small pinion on the countershaft to the rear driving wheel. There were two batteries, one containing Mildé accumulators and the other Fulmen; moreover, one of the batteries was old and the other new. To make matters worse, the accumulators polarised through bad charging. and for most of the time the van was in the tent undergoing repairs. The only time it finished a route it was followed by a portable engine with a dynamo, and this precaution was a wise one, for the batteries had to be re-charged on the road to enable the van to return to Versailles. The greatest interest was taken in the trials by delegates from local bodies all over the country, and the Minister of War ordered a large number of officers to follow them with a view to ascertaining whether motor cars could be profitably employed for military purposes.

Automatic Pressure Regulation on a Three-Phase System.—An interesting method of regulating the voltage at the terminals of the rotary transformers, which furnish power to the shops of the General Electric Co. at Schenectady, is described in the *Electrical World* of Oct. 1. The three-phase current is transmitted from Mechanicville as described in an

Digitized by Google

article in our issue of Oct. 7, and is transformed to continuous current by means of stationary step-down and rotary transformers. The transmission line has considerable self-induction, and the rotaries are compound wound, the series winding being heavy, and the shunt-winding being, at no load, insufficient to generate at synchronous speed a back E.M.F. sufficient to choke back the impressed alternating-current waves. The result is that wattless currents lagging behind the impressed E.M.F. enter the rotary armature and automatically increase the field excitation to a proper value. These lagging currents react upon the self-induction of the line, causing a drop considerably greater than that due to its resistance alone, and—the direct-current voltage being practically proportional to the impressed alternating voltage at the rotary rings—the reduction of the latter by means of the increased line drop prevents too great a pressure being delivered from the direct-current end on no load. As the load rises, however, the action of the series fields of the rotaries begins to assert itself, and the wattless currents in the armature necessary to maintain the field excitation fall off, until at a point about three-quarter-load the power factor of the incoming current approaches unity. As the load further increases the line drop is diminished, and the leading current and line inductance may even be sufficient to boost up the volts to a greater value than at the receiving end. This arrangement alone would be sufficient to obtain proper voltage regulation but for the interference of the load taken by the synchronous motors driving the generators of the testing department. Any increase of the load in this department increases the current in the line, consequently increases the ohmic or resistance drop without the proper compensating effect in the wattless currents taken by the rotary. To make the rotaries take leading or lagging currents which shall balance out the disturbing effects of the synchronous machines the following system has been devised. The rotary shunt fields are excited from a separate direct-current 'bus bar which is fed with current from the main 'bus through an auxiliary exciter. This auxiliary exciter serves to raise the voltage across the rotary fields, and is driven by an alternating-current synchronous motor of the same number of poles, thus keeping its armature in step with the alternating system. It has no field exciting winding, but its armature is fitted with three collecting rings, into which alternating current may be introduced from the secondaries of three small series transformers, the primaries of which are inserted in the lines feeding the synchronous motors. The armature of the auxiliary exciter is coupled to the synchronous motor at such an angle that the currents introduced from these series transformers, when the load passing through their primaries is of unity power factor, tend to set up a field of force in the magnetic circuit of the auxiliary exciter, and build up a direct-current voltage across its brushes; thus, the greater the load on the motors in the testing department the greater is the boosting action of the auxiliary exciter.

The Utilisation of Blast-Furnace Gases.—In the course of an interesting article on this subject in the October number of *Cassier's Magazine*, Mr. H. Savage, of the Société John Cockerill, details some experiments made at that company's works at Seraing. Some of these results have already been given in a Paper read before the Iron and Steel Institute by M. A. Greiner. Trials lasting over two years were made at Seraing by MM. Bailly and Kraft. The first machine experimented with was a small 8 H.P. "Simplex" gas engine of the type patented by Messrs. Delamarre-Debouteville. This engine ran for a period of 18 months, but developed only 4 effective horse-power. Later on, after modification of a few details, the full 8 H.P. were attained. The gas consumption was certainly high, but with the engines working at full load there was no doubt it could be materially reduced, and it was expected that a consumption of 105 cubic feet per hour per indicated horse-power would not be exceeded in a large 200 H.P. engine recently started. This engine was designed by M. Delamarre and constructed in the Company's shops. The supply of gas is taken from the blast-furnace mains and led through three pairs of coke scrubbers, in which it is thoroughly washed by being brought into contact with water driven into the scrubbers in the form of spray by Körting injectors. After washing, the gas may be sent direct to the engine, although a gasometer exists to serve the purposes of a regulator and reservoir. The engine has one working cylinder, 800 millimetres (31 $\frac{1}{2}$in.) in diameter, with a stroke of one metre (39·37in.). It is of the usual four-stroke, or Beau de Rochas, cycle type, each explosion corresponding to two forward and two backward strokes of the piston. The working speed is 100 revolutions per minute, and to insure regularity the engine is fitted with a heavy fly-wheel, weighing about 15 tons, and a counterbalanced crank, besides which a pendulum governor, acting on the gas inlet valve, restrains any tendency towards excessive speed. The initial compression in the cylinder reaches about 115lb. per square inch. The gas is ignited electrically. Trials of this engine, conducted by the well-known expert, M. Aimé Witz, have given the most satisfactory results. During a continuous run of 24 hours an almost constant power of 180 I.H.P. was maintained, on a remarkably low consumption of gas, equivalent to about 115 cubic feet per hour and indicated horse power. The conditions of the trial were those of ordinary work, no attempt being made to drive the engine to the extreme limit of its power. A second 200 H.P. engine at present building at Seraing is to be adapted to electric driving. The present one drives an air-compressor. The objection based on the presence of dust in the gas was one to which Mr. Lürmann gave great prominence at a recent meeting of the German iron and steel makers at Düsseldorf, and one which is by no means minimised by the nature of the gas given off by the Seraing furnaces, in which purple ore is very largely used. It was found, however, that the small 8 H.P. engine was able to run for four months continuously without cleaning, and the new large engines are supplied with far better means of getting rid of the dust. Gas absolutely free from dust is, says Mr. Savage, no more a necessity with gas engines than distilled water is in the case of steam engines. No inconvenience was experienced from corrosion of internal parts. Finally, the irregularity in the composition of the gas, which was expected to be the great drawback, loses much of its apparent gravity in the light of practical experiment. Gas so poor in combustible ingredients as to be practically useless for heating boilers still gives fairly satisfactory results with a new motor, which seems to adapt itself readily to considerable differences in the quality of its fuel. At Wishaw, in this country, gas from furnaces burning raw coal is utilised for driving an electric lighting plant, after the separation of the tar and ammoniacal waters, and Mr. B. M. Thwaite, the designer of this plant, is said to have been equally successful with gases from blast furnaces using coke. The Westinghouse Co., in the United States, have also had on trial a 750 I.H.P. gas engine for some time past.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, November 7th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall.

TUESDAY, November 8th.

LONDON INSTITUTION.

5 p.m. Lecture at Finsbury-circus on "Fire and Fire Extinction," by Prof. Vivian B. Lewes.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read and discussed: "The Extraction of Nickel from its Ores by the Mond Process," by Prof. W. C. Roberts-Austen, F.R.S.

THURSDAY, November 10th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when Prof. Silvanus P. Thompson, F.R.S., will read a Paper on "Rotatory Converters."

FRIDAY, November 11th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda:—(1) Discussion on Mr. A. Campbell's Paper on "The Magnetic Fluxes in Meters and other Electrical Instruments"; (2) "On the Propagation of Damped Electrical Oscillations along Parallel Wires," by Prof. W. B. Morton; (3) "On the Properties of Liquid Mixtures," by R. A. Lehfeldt.

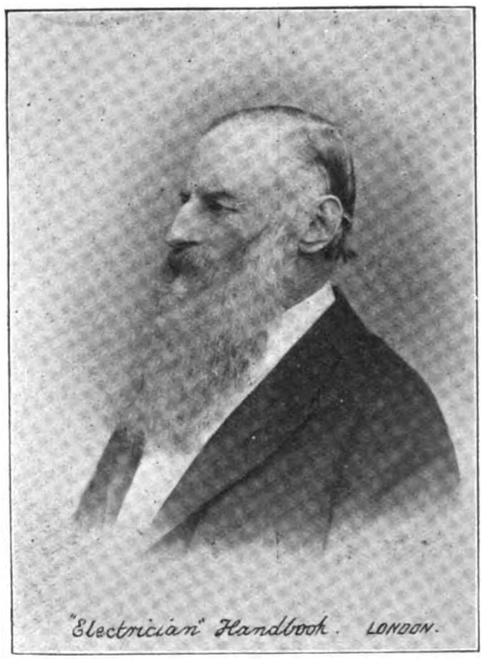
OBITUARY.

LATIMER CLARK.

It is with profound regret that we announce the death of Mr. Latimer Clark, C.E., F.R.S., which took place quite suddenly at his residence at Twickenham, on Sunday morning last at about 7:30. The announcement of Mr. Latimer Clark's death will be read with sorrow by a very wide circle of our readers, and we desire to take this opportunity respectfully to tender our sympathy with his family and the numerous friends who mourn his loss.

Latimer Clark was born at Great Marlow on March 10, 1822, and attained, therefore, the ripe age of 76 years. Although principally known to the world at large in connection with his prominent association with submarine telegraphic enterprise and the construction of submarine cables, Mr. Clark was at first connected with the chemical manufacturing industry, after which he commenced railway surveying in 1847, and was appointed assistant engineer for the construction of the Britannia tubular bridge across the Menai Strait, the resident engineer being his brother, Mr. Edwin Clark. It was on this occasion that he applied electricity for the purpose of firing a time gun every evening at eight o'clock, which attracted the attention of the chairman of the Electric Telegraph Co., who, in 1850, appointed Mr. Clark to the post of assistant engineer to that company, under his brother. Later on he became their chief engineer and consulting engineer. It was thus that he entered upon his association with telegraphic enterprise, in which he has played such a conspicuous and useful part. Connected in the first instance with land telegraphy, Mr. Clark introduced many improvements in the telegraph system, and in 1860 a report by him on the subject of underground telegraph wires was prepared and was embodied in the Government report on the subject in 1861. It was he who first detected the retardation of signals owing to induction in submarine and underground lines, a discovery which led him to investigate the question of the transmission of signals, and to demonstrate that electric currents of low voltage travel at the same speed as those of high voltage. As an instance of one of the details of the numerous improvements in the construction of overhead telegraphy which Mr. Clark introduced, we may mention the double-cup insulator which he invented and patented, and which is now extensively employed all over the world. To him also we owe the invention, in 1854, of the now largely used system of transmitting messages through tubes pneumatically. In 1858 he applied to practical use the experiments which he had been making in the protection of submarine cables by a compound well known as "Clark's compound." The subject of submarine telegraphy was at about this date one of national interest, and in 1860 Mr. Clark was nominated a member of the committee jointly appointed by the Government and the Atlantic Cable Telegraph Co. to inquire into the whole subject of submarine telegraph cables; and in this capacity he rendered very great assistance to the cause of submarine telegraphy; for, in addition to the help he gave as a member of the Committee, he drew up and submitted a valuable report on technical matters connected with submarine signalling, and embodied the researches and experiments that had been made up to that date. About this time—*i.e.*, 1860—Mr. Latimer Clark went into partnership with Sir Charles Bright, and for 10 years carried on under this partnership extensive work in the construction and laying of submarine cables. In conjunction with his partner he read a Paper before the British Association at Manchester, in September, 1861, putting forward a definite system of electrical measurement in ohms, volts and farads, the heterogeneous and unscientific systems of measurement until then in vogue being thereafter gradually displaced by the system these electricians propounded, which practically forms the basis of modern electrical scientific measurement. In fact it was this Paper which led to the formation of the British Association Committee on Electrical Units, which since that date has done so much useful work. In foreign work, Mr. Clark was for many years engineer to the Indian Government cable lines in the Persian Gulf; and his researches during this period on the effect of temperature on the insulation of gutta-percha cables, made in conjunction with his partner, Sir Charles Bright, in 1863, proved of great value for practical telegraphic use. Their table embodying these researches is, indeed, still in daily use. It should not be forgotten that Mr. Clark was the inventor of the well-known and most extensively used standard cell which bears his name, a standard which is equally of service in heavy electrical engineering as in telegraphic practice. We may here mention that in addition to scientific and practical work, Mr. Latimer Clark was the author of several important contributions to scientific literature. His "Elementary Treatise of Electrical Measurements," which appeared in 1868, has from that date been a standard work on the subject. A few years later, in conjunction with Mr. Sabine, he published his work on "Electrical Tables and Formulæ." He is also the author of several astronomical works.



LATIMER CLARK, C.E., F.R.S.

As head of the well-known firm of consulting engineers, Messrs. Clark, Forde and Taylor, Mr. Latimer Clark has been connected with the submergence of some 100,000 miles of submarine cables in all parts of the globe. For a number of years he was also a partner in the engineering firm of Clark and Standfield, and in the late firm of Latimer Clark, Muirhead and Co., in which he brought out many important improvements in various branches of engineering. Up to the time of his death Mr. Latimer Clark remained head of the firm of Messrs. Clark and Standfield, the well-known dock engineers.

In recognition of his services to engineering and scientific advancement, as well as to the community at large, he had numerous honours bestowed upon him. He was a Chevalier of the Legion d'Honneur, a Fellow of the Royal Society and Past-President of the Society of Telegraph-Engineers and Electricians, having held the office of President in the year 1875, before the change of name.

Mr. Latimer Clark was at his office in Victoria-street, Westminster, on Friday, last week, apparently in his usual health. He complained in the night of Saturday of indigestion, and took a slight stimulant to ward off the attack. As above stated, later (at 7:30 a.m.) he was found to have expired in his bed.

Mr. Clark was buried yesterday (Thursday) at the Kensington Parochial Cemetery, near Hanwell, Middlesex. Several members of the Council and other members of the Institution of Electrical Engineers were among the mourners present at the grave.

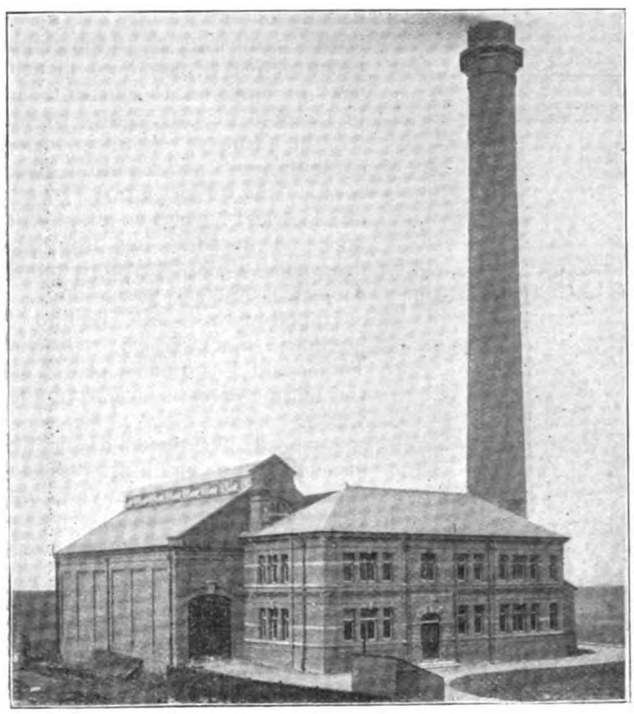
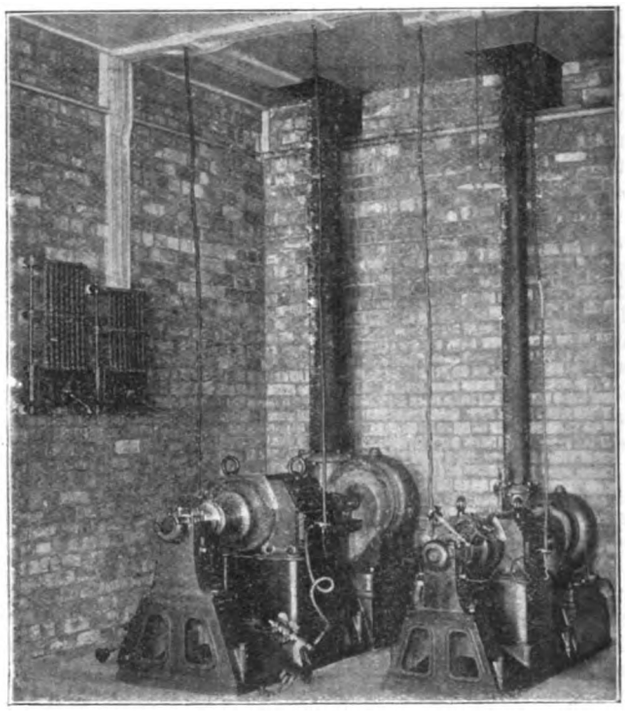
HULL MUNICIPAL ELECTRIC SUPPLY WORKS.

As announced in our issue last week, the electric supply works of the Hull Corporation have recently undergone considerable extension, in the opening of a new generating station, at Sculcoates-lane. The history of the electric light undertaking in Hull is, briefly, as follows:—In 1887 an electric lighting committee of the Corporation was formed, and on August 4th of the following year an electric lighting order was obtained. Mr. R. E. Crompton was engaged to report on a scheme, and recommended, in 1891, a low-pressure scheme at an estimated cost of £16,000. This was followed by the appointment of Mr. F. Harman Lewis as borough electrical engineer, the Crompton scheme being immediately proceeded with. This scheme included a generating station in Dagger-lane, with engines aggregating 560 H.P., built by Messrs. Willans and Robinson, direct-coupled to Siemens dynamos of 300 kilowatts capacity. The boilers of this station were supplied by Messrs. Davey, Paxman and Co., and the original plant included accumulators of the Crompton-Howell type, and about 2¼ miles of mains laid on the Crompton system. On June 16, 1893, these works were opened, and have since run continuously with complete success. There were 83 consumers connected at the time of the inauguration, and an equivalent of 600 lamps. During this year Mr. Harman Lewis was appointed to the post of Corporation electrical engineer at Wolverhampton, and was succeeded, at Hull, by Mr. A. H. Gibbings, now of Bradford. Also during this year considerable extensions of mains took place, about three miles of mains on the Callender-Webber system being laid. In the following year the plant at the Dagger-lane station was extended by the installation of a 300 H.P. Willans engine and a 180 kilowatt dynamo by Messrs. J. H. Holmes and Co., and in the next year a similar extension of plant took place. In October, 1895, Mr. Gibbings left, and Mr. A. S. Barnard was appointed in his stead, a post Mr. Barnard still retains.

Owing to the rapidly increasing demand for current, it became necessary, in June, 1896, to consider a scheme for very extensive additions to the electrical supply system, this scheme being estimated to cost £42,000. Unfortunately, it was twice rejected by the Town Council, but in December of the following year Mr. Hammond's report on the scheme was submitted for a third time, and finally accepted by the Council, with the addition of £10,000 to the estimate for the district of East Hull. At this time, the number of consumers connected was 520 and the capacity of the plant 26,817 lamps. No less than 340,339 units were sold during the year 1896, a profit of £1,970 being made on the year's working. The new works were pushed on with, but owing to some delay in starting them and to the increased number of applications for current, temporary works had to be laid down in 1897, these commencing supply in conjunction with the Dagger-lane station. The temporary works ran from Nov. 5th until March 5th following, when the capacity of the Dagger-lane station was increased to 1,160 H.P. in engines and 660 kilowatts in dynamos. The present capacity of the new station in Sculcoates-lane, together with the sub-stations at Argyll-street and Albion-street, is 760 H.P. in engines and 456 kilowatts in dynamos, but there are 750 H.P. in engines at present under order together with 450 kilowatts in dynamos. At the present date, there are 863 consumers connected to the mains and lamp connections aggregate 67,900, while no less than 16½ miles of mains have been laid, including the 3¼ miles now actually being laid. The customers include a great variety of consumers, there being, in addition to the ordinary lighting consumers, a fairly large motor load for printing and other work. We will now proceed briefly to describe the equipment of the new station and the sub-stations which have been recently erected.



Hull Municipal Electric Supply Works. Sculcoates-lane Station.



Motor-driven Centrifugal Pumps at Sculcoates-lane Station.

Boiler Room.—In the boiler room there are at present erected two Lancashire boilers by Messrs. Tinkers (Limited), of Hyde, each being 30ft. in length and 8ft. in diameter, together with a Babcock-Wilcox boiler of 150 H.P. The last-named boiler has 1,218 sq. ft. of heating space, composed of six sections, each section having nine tubes 4in. diameter and 18ft. long. The headers are made of wrought steel, and the drums are 36in. diameter and 23ft. 7in. long. The boilers work at 150lb. pressure. All the boilers are at present hand fired with the best South Yorkshire steam coal. In conjunction with the boiler plant there is a Green's economiser, composed of 192 tubes, arranged in two groups, coupled together by expansion elbows, and tested to 350lb. pressure. The feed pumps are of the direct-acting vertical type, with the pump underneath. They throw their supply from a tank filled with softened water, a water softener of the Pemberton type being used, together with a clarifying or filtering tank and apparatus for thoroughly mixing the re-agent solution with the water to

Digitized by Google

be softened. The feed supply is arranged on the duplicate ring main system, similar to that employed for the steam ranges, and arranged so that any pump can supply any boiler either with cold or hot water. In addition to the feed pumps there is also an independent injector feeding gear, which can be used either in conjunction with the pumps or otherwise. The water for the feed, as well as for the condensing plant, is pumped out of an adjacent drain by means of two centrifugal pumps 5in. and 7in. in diameter, and is discharged into a large overhead tank of 29,120 gallons capacity. Each pump is driven independently by an electric motor by Thomas Parker (Limited). From this tank the water is supplied to the two ejector condensers through a 12in. pipe. The exhaust from the engines can be turned either into the condensers or into an atmosphere pipe of 15in. diameter which runs along under the floor and is carried upwards outside the building. The steam ring consists of two parallel lines of 8in. wrought iron solid drawn pipe, with welded flanges resting on cast-iron chairs behind and above the boilers and connected at the ends with copper U bends of the same size as the pipe. Into this ring each boiler feeds by a separate copper pipe bent into an S shape so as to avoid strains due to expansion. The standpipes are each provided with a complete set of valves enabling each boiler to be used independently, an arrangement which is also applied to the engines running off the ring mains. The plane of the ring is inclined downwards towards the boilers, and it is drained at two points by steam traps. Messrs. Thomas Parker (Limited) have erected one 30 B.H.P., and one 14 B.H.P. shunt motor, coupled to centrifugal pumps for condensing purposes; also one 2 B.H.P. shunt motor for driving the economiser scrapers, all the motors running off the 220 volt circuit.

Machinery Room.—In the machinery room there is erected high and low-pressure continuous-current plant, having an aggregate capacity at present of 456 kilowatts. The low-pressure plant consists of two Willans engines of the G.G.S. type, each indicating 100 H.P. under 140lb. steam pressure. These engines run at 450 revolutions, and are coupled direct to two-pole dynamos by Messrs. Thomas Parker (Limited), each dynamo giving 130 amperes at 300 volts. These machines are for the supply of local consumers; also for the pump and economiser motors on the works. The motor generator is also installed in the building, and is used for balancing purposes or for supplying light loads in conjunction with the battery. The high-pressure plant consists of two Willans engines of the I.I.I.S. type, capable of developing 360 H.P. at the same pressure when running at 350 revolutions per minute. These are coupled direct to two-pole dynamos, by Messrs. Thomas Parker (Limited), each giving 90 amperes at 2,250 volts. These generators are separately excited from a 225 volt circuit. The armatures of these machines are wound on the Eickemeyer principle. All the engines are fitted with Messrs. Willans and Robinson's automatic expansion gear, and a separate condenser is provided for each engine, the condensers being of the Körting injector pattern, and arrangements are made so that each set can be run either condensing or non-condensing, as required. A 10 ton hand-power travelling crane spans the engine room.

Switchboards.—The switchboard equipment consists of two separate switchboards for the high and low-pressure plant respectively. These have been made as nearly as possible fireproof, being composed of 1½in. slate slabs mounted on iron frameworks. The low-tension board contains two dynamo panels, one battery panel, two feeder panels, one Board of Trade panel, one motor-generator panel, and one works distribution panel. Each dynamo panel is fitted with a Weston ammeter and voltmeter, a D.P. switch with maximum and minimum control, a throw-over main switch and field regulating switches. The battery is placed on one side of the three-wire system and 18 regulating cells are connected to the switchboard. All motors, lights, &c., on the works are connected to throw-over switches on the works distribution panel, so as to enable them to be run from either side of the system. Thomson-Houston wattmeters are installed in the low-tension feeders both here and at the sub-stations, so that all current delivered to the distributing mains is metered.

The high-tension switchboard contains two dynamo panels, one Board of Trade panel and six feeder panels, and four spare panels for extensions are provided. Each dynamo panel contains a Weston ammeter, a Kelvin voltmeter, a D.P. switch with maximum and minimum control, and field regulating switches. The dynamos are connected by the D.P. switches to the high-tension 'bus bars, from which the feeders are tapped. The feeder panels each contain a Weston ammeter and voltmeter, a D.P. switch with maximum cut-out, and transformer starting and regulating switches. The voltmeters on the feeder panels are connected to the feeding points on the low-tension mains, and the pilot wires are connected to them *viâ* the shunt coil of a long range switch on each transformer. By short-circuiting the voltmeter about 5 amperes is made to pass through this coil, and the long range switch is actuated, connecting a transformer to that particular feeding point. A repetition of the process throws the switch into the "off" position.

Battery Room.—The battery room at the main station contains 126 Pritchett and Gold 11-plate cells in glass boxes. The capacity of this battery is 300 ampere-hours at 225 volts.

Sub-Stations.—There are at present two sub-stations, one at Albion-street and one Argyle-street. The building at Albion-street was specially designed for the purpose, and contains two 90 kilowatt rotatory transformers and a motor generator. Room for an extension of the plant is provided. At Argyle-street four railway arches have been utilised, two of which are used as stores for the outdoor department, one as a battery room and one as a transformer chamber. In the battery arch there are 240 Pritchett and Gold cells similar to those at the generating works. These are charged in three sets of 80 cells off the distributing mains, and are discharged in two sets of 120 cells. The switchboard is situated in the transformer arch, where there are two 90 kilowatt and two 45 kilowatt machines with the necessary switches, &c. The 90 kilowatt transformers are wound for a step-down from 2,250 to 450 volts, and the two smaller transformers are wound for 2,250 to 225 volts. The 90 kilowatt transformers at Albion-street supply a portion of the old network and are wound for 2,250 to 225 volts, the motor generator forming a connecting link between the old 220 volt three-wire and the new 440 volt three-wire networks. The transformer armatures are of Messrs. Parker's usual type with high and low-tension winding on the same core and with a commutator at each end. They are "Eickemeyer" wound, with an earthed metallic shield between high and low-tension windings. The lubrication is effected by a force pump on each bearing, and the machines can be run for long periods without attention.

Mains.—The mains extensions have been carried out by Messrs. Siemens Bros. and Co., and consist of six high-tension circuits running from the generating station in Sculcoates-lane to the two sub-stations, and low-tension feeders running from the generating station and these sub-stations to various points in an extensive network of distributing mains. The high-tension feeders, pilot and telephone wires are drawn into Doulton's stoneware conduits. These conduits are made in 3ft. lengths, and are jointed together by means of stoneware cradles with Portland cement; no less than 45,000 yards of 2¼in. by 2¼in. duct has been used, spare ways being provided for future extensions. Draw-boxes built of 9in. brickwork on concrete foundations are provided at all corners and bends and where otherwise necessary, and they are provided with cast-iron frames and covers, and are ventilated by means of a stoneware pipe connected to a small ventilator frame. The high tension feeders (of which about 17,000 yards have been laid) are 0·06 sq. in. and 0·03 sq. in. sectional area, concentric, insulated with impregnated fibrous material, lead-covered and externally taped and compounded. The low-tension feeders consist of about 4,600 yards of 0·5 sq. in. concentric lead-covered cable, armoured with two layers of 0·05in. hoop-iron, and is laid direct in the ground. Three nine and 12-core pilot wires are laid alongside the feeders, and a four conductor "dry-core" (air-space) telephone cable permits of communication between the generating and sub-stations.

About 24,000 yards of distributors have been laid of the triple core, impregnated fibre insulated lead-covered and armoured

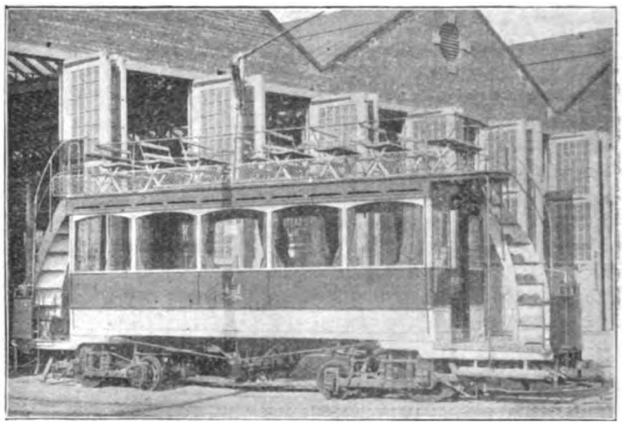
type, the positive and negative conductors being 0·15 sq. in. section. The advantages of this class of distributing main for three-wire systems are now universally recognised. It combines flexibility with facility of jointing, the service and other boxes employed being of a much simpler construction than those for triple concentric mains. It was first made by Messrs. Siemens for the Bolton Corporation some years ago, and has since been advantageously adopted by many Corporations.

All the cables, before and after laying, have been subjected to exhaustive tests with satisfactory results. The straight joints are made in cast-iron boxes in two halves bolted together. The internal fittings consist of copper sleeves and sockets for sweating the conductors into, and are embedded in the hard-setting insulating compound with which the boxes are filled. About 60 disconnecting boxes, both of three-way and four-way patterns, have been inserted in the network, and allow of any section of the distributor being rapidly cut out or disconnected for testing purposes. The internal fittings of these boxes are so arranged that either disconnecting copper links or fuses can be used. They are set in brick pits, with manhole frames and covers of similar construction to the draw boxes. The service cables are of the twin pattern, india-rubber insulated, lead covered and armoured, and are connected to the mains through cast-iron T boxes.

In conclusion, we have pleasure in tendering our best thanks to Mr. A. S. Barnard, the Corporation electrical engineer at Hull, and to the several contracting engineers, for much of the information embodied in this article.

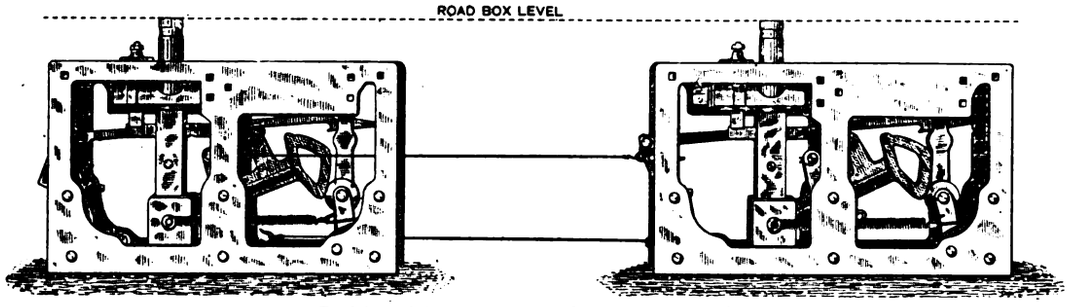
THE "ANDERSON" CLOSED-CONDUIT SYSTEM OF ELECTRIC TRACTION.

The closed-conduit system invented by Mr. Christopher Anderson, and now being tried upon a short length of experimental tramway at Leeds, represents another and somewhat older attempt than the one we described last week to discover a satisfactory system of electric traction that should avoid unsightly overhead equipment, on the one hand, and, on the other hand, open slots or cavities in the roadway. This system, which we purpose briefly to describe in this article, differs from the class of closed-conduit systems to which belong the Thomson-Walker, Westinghouse and allied systems, in that the surface contact pieces on the roadway are not fixed, but are capable of no less than 4in. of vertical motion. When no electric car is over any one such contact piece it is, in the ordinary course, in its lowest position and out of the way of ordinary vehicular or pedestrian traffic; it should, therefore, in this circumstance, possess no element of danger. When an electric car glides over the contact piece the latter is automatically raised above the ground level and projects sufficiently to come into contact with a collector

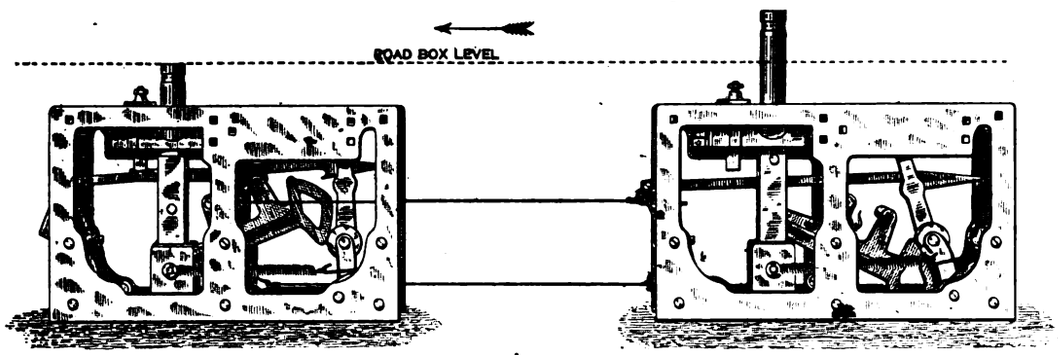


Trolley Car equipped for working on the "Anderson" Closed-conduit System as well as on the Overhead Trolley System, at Leeds.

carried on the car at a much greater clearance than usual. Simultaneously with the elevation of the contact rod it is made electrically alive, it being in all other positions inert. On the passage of a car beyond the elevated rod the rod is arranged, in the ordinary course, to fall into the position of safety; but it will be evident that failure of it to do so would expose upon the roadway a metal rod projecting 4in. above the surface, and in a dangerous condition of electrification. Consequently, the essential feature of the system in regard to guarantee of safety must be to ensure that such an occurrence would be impossible. Although the short length of experimental line has been working satisfactorily for some short time, it is rightly felt by the authorities interested in the development of electric traction in Leeds, and especially by Mr. Hannam, the Chairman of the Tramways Committee, that a definite opinion in favour of the system cannot be pronounced until it has been tried for a lengthy period in all sorts and conditions of weather. It is of the utmost importance to



Position of Contact Pieces when not in operation.



Position of Contact Pieces when actuating car.

Digitized by Google

determine whether frost or wear-and-tear can interfere with the falling of a plug into the safe position when a car has passed from over it. Nevertheless, the system possesses many points of novelty, and exhibits great ingenuity in its design and construction. The cost of the surface-contact boxes, we are informed by the inventor, is £600 for the half-mile of experimental line; but it is expected that this figure will be considerably reduced when the boxes are turned out by machinery in large quantities.

NOTES ON THE TURIN INTERNATIONAL EXHIBITION.

(BY OUR OWN CORRESPONDENT.)

(*Continued from page 751.*)

Messrs. Siemens and Halske, of Berlin, who have erected electric lighting plants in many Italian towns, have naturally a fairly large exhibit, but so far as dynamos and motors are concerned there is very little of real novelty. Among their machines I may mention two large continuous-current dynamos, working at 480 volts and 400 amperes, directly coupled to the engines. These machines are of the old type, with internal field magnets and external armatures and commutators. This firm also exhibits some other dynamos, a transformer, a car motor, and three-phase motors of smaller sizes. There are also many interesting measuring instruments, which will be referred to later on.

Some well-designed machines, although not comprising any particular novelty, are exhibited by Messrs. Guzzi and Ravizza, of Milan. These include a series of three-phase motors and a large 300 H.P. 3,000-volt alternator, with its exciter. This firm also exhibits a model of an oscillometer adopted by the Italian navy for measuring the oscillations of a ship. Fig. 4 shows the instrument in section, elevation and plan. The armature of an electric motor is suspended by a balanced suspension, and rotates at a very high speed. The armature is weighted by a heavy brass ring, which acts as a gyroscope, and, its centre of gravity being placed in the centre of the suspension, its position does not change when the ship rocks. Attached to the motor are two pointers, H_1 and H_2, moving along graduated scales, F_1 and F_2. These scales are fixed to the two axes of suspension of the apparatus, and when the ship is still, one of them lies in the vertical plane passing through the axis of the ship, while the other is at right angles to it, and the two pointers are at the zeros of the scales. When the ship oscillates, the two scales oscillate with her and the amplitudes of the oscillations are shown on the scales.

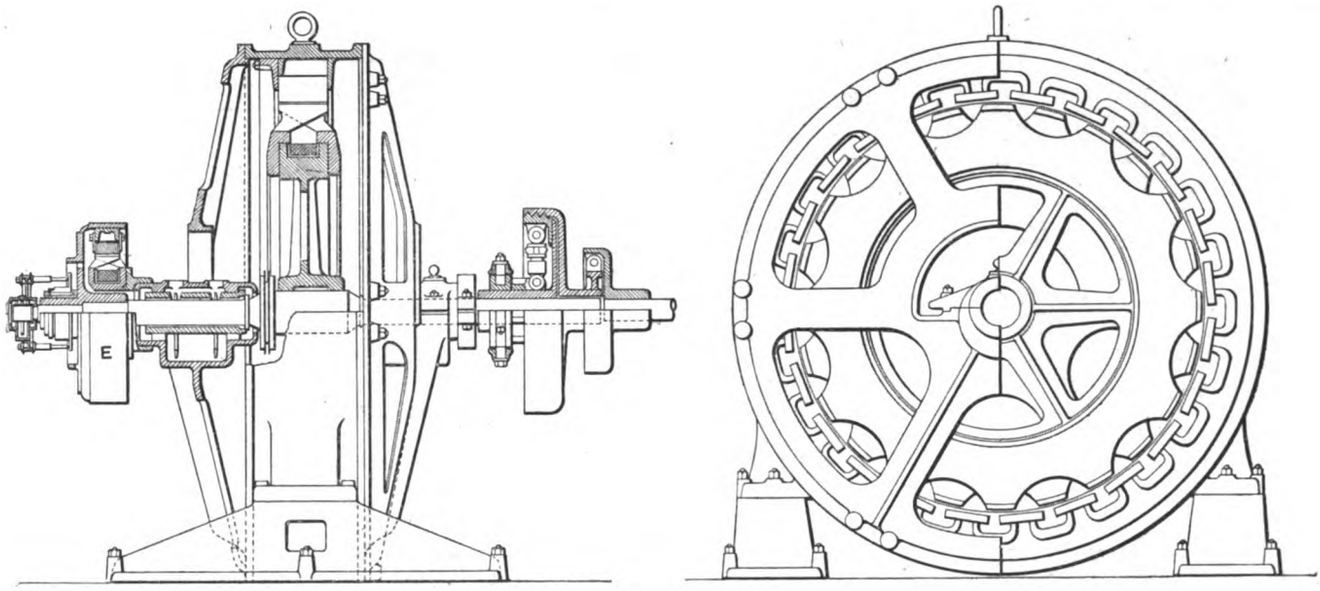


FIG. 5.—Caramagna and Ambrosetti's Alternator.

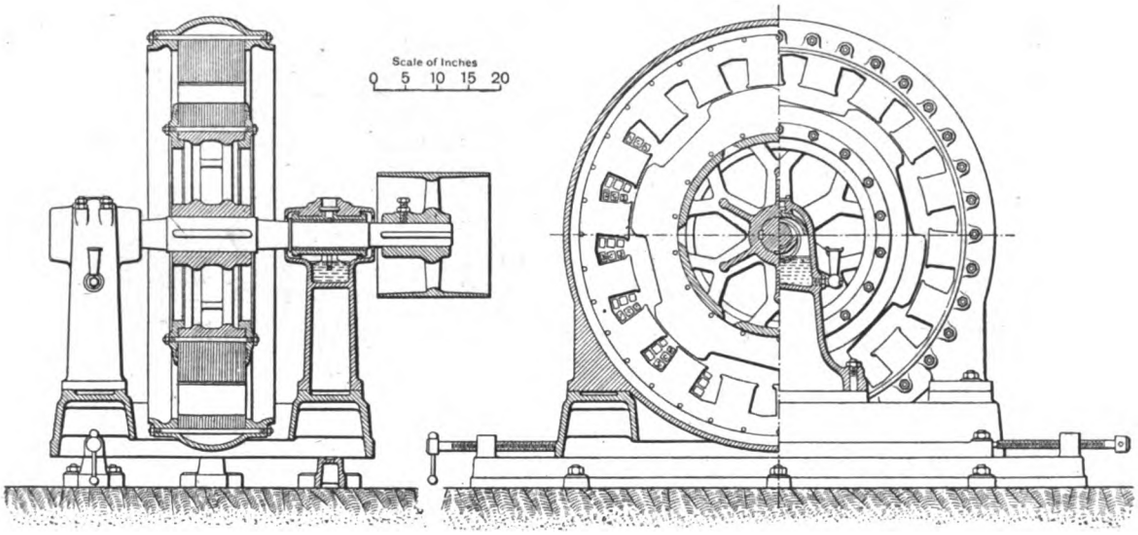

FIG. 6.—150-H.P. Three-phase Alternator constructed by Messrs. Brioschi, Finzi and Co., of Milan.

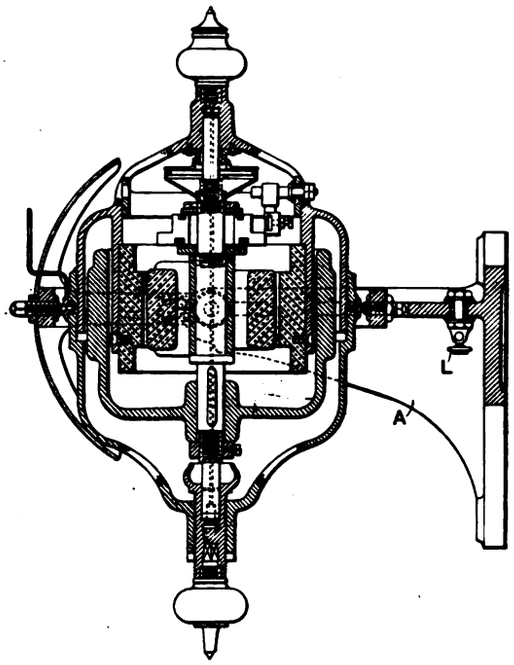
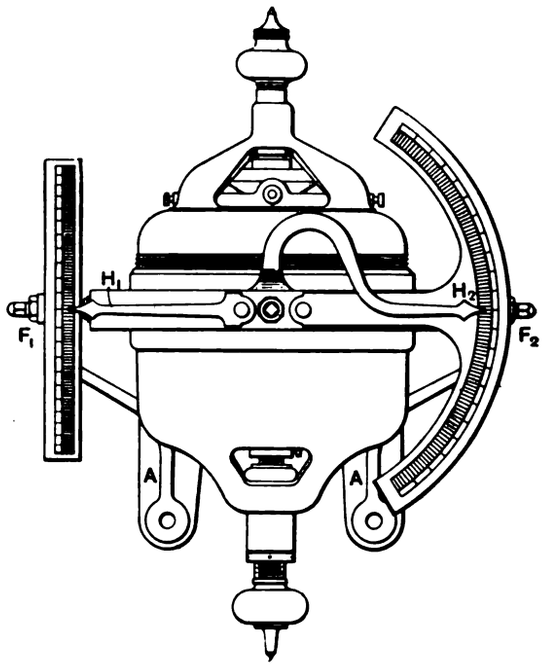
Messrs. Caramagna and Ambrosetti, of Torino, only exhibit one machine, but of an entirely new design. It is a 250 H.P. two-phase alternator, working at 4,000 volts, and is connected directly to a shaft by means of a friction clutch. The machine is shown in Fig. 5. The field magnets rotate, and as can be seen in the drawing, there are two crowns of 24 poles, between which the winding lies. Although each north pole lies

Digitized by Google

between two south poles, their shape is such that all the poles present the same outside surface. The annular armature has 24 laminated cores, and the exciter E, which is built on the same shaft, has four field magnet poles very similar to those of the alternator. But in this case the annular armature is keyed to the shaft and revolves, while the internal field magnets are stationary. Incidentally, I may mention the switch used for controlling this machine. The moving parts form a parallelogram, of which one link is a long glass bar and takes the place of the usual hand lever.

Messrs. Finzi, Brioschi and Co., of Milan, have a number of entirely new designs. Their largest piece of machinery is the 150 H.P. three-phase inductor alternator, shown in Fig. 6, which works at 900 volts. As seen in the drawing, the stationary part has 18 pole-pieces projecting inwards. Each of these poles holds two armature coils, and the field coils are sandwiched between them. The inductor has six poles. The lavish use of soft iron in the design of this machine is especially noticeable. Broadly speaking, it may be said that the entire magnetic circuit is of this material, cast iron





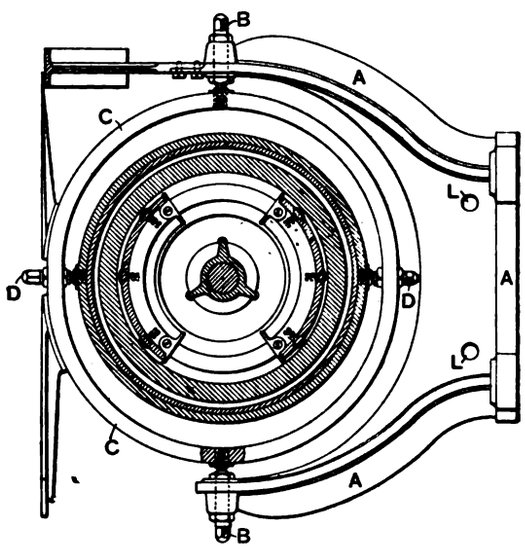


FIG. 4.—Messrs. Guzzi and Ravizza's Oscillometer.

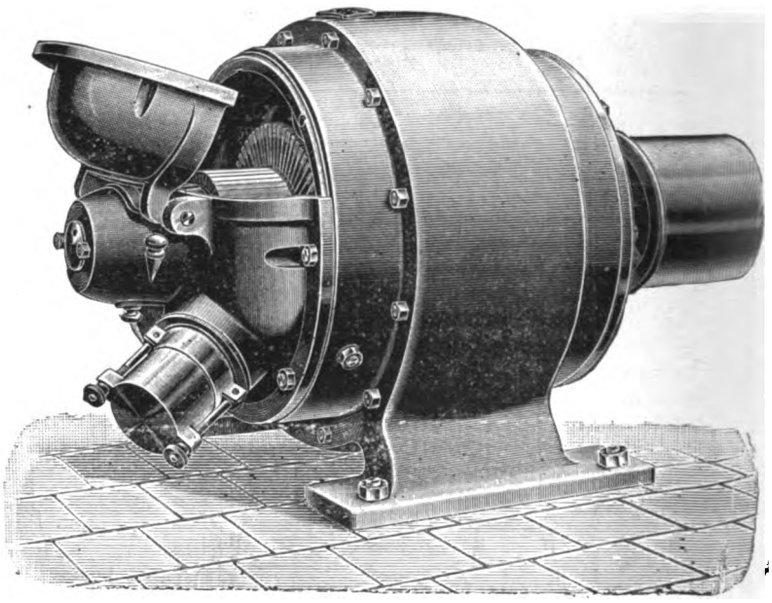

FIG. 7.—Enclosed Motor built by Messrs. Brioschi, Finzi and Co.

Messrs. Morelli, Franco and Bonamico, of Turin, have a very good display of dynamos and motors, both for continuous and three-phase currents. One iron-clad continuous current motor, which is claimed to be perfectly watertight, is of special interest. The motor is entirely enclosed and has a window through which the brushes can be inspected, and a device for adjusting them without opening the case. In order to demonstrate that the machine is absolutely watertight, and at the same time to attract the attention of visitors, a fountain is throwing water over it throughout the day. The same firm also exhibit a very fine switchboard designed for three-phase central stations.

only being used as a mechanical means of holding the parts together. Both armature and field windings are very easily removable. The firm makes a speciality of dust-proof motors, and exhibits various sizes both for continuous and three-phase currents. The smaller sizes of the three-phase machines are fitted with self-contained gears to reduce the speed to about 200 revolutions per minute. The continuous-current motors have the peculiarity that their field-magnets are made of laminated iron, the laminations being in the direction to interrupt the cross magnetising lines of force induced by the armature reaction. By this means, it is stated, the necessity for adjusting the brushesis quite obviated, the machine

Digitized by Google

running sparklessly with the same position of the brushes at no load and full load. An external view of one of these motors is shown in Fig. 7.

The Societa Bacini di Carenaggio of Genoa exhibits a number of machines especially designed for ship lighting. These are directly coupled to vertical steam engines, and range in capacity from 5 to 200 kilowatts.

One of the largest collections in this exhibition is that of the Officine di Savigliano. This firm has a 70 H.P. 4-polar continuous-current dynamo running, driven by a gas engine. A fine, well-designed, and apparently very light two-phase dynamo of 66-kilowatt capacity, and working at 110 volts pressure, is also on view. The greater part of this firm's exhibit is in the various mechanical applications of electricity, and I will refer to these later.

(*To be continued.*)

THE INTERNATIONAL MAGNETIC CONFERENCE.*

The Committee on Terrestrial Magnetism and Atmospheric Electricity appointed at Paris in September, 1896, consisted of eight members. These gentlemen found that it was desirable to add to their number, by co-option, and the constitution of the Committee is now as follows :—(Appointed at Paris) Prof. Rücker (President), Prof. Eschenhagen, Prof. Liznar, M. Th. Moureaux, Sig. L. Palazzo, Dr. Paulsen, Dr. Van Rijckevorsel, General Rykatcheff ; (Co-opted) Dr. Bauer, Prof. W. Von Bezold, Sig. Brito-Capello, Dr. Carlheim-Gyllenskjold, Prof. Mascart, Prof. T. Mendenhall, Prof. A. Schmidt, Dr. C. Schott, and Prof. A. Schuster.

International Conference.—In consequence of a suggestion, made originally by Prof. Schuster, that arrangements should be made for an international conference of those interested in terrestrial magnetism, the Committee decided to summon such a conference; and the hospitable invitation of the British Association, to hold the meeting in connection with that of the Association at Bristol (September 7-14, 1898), was accepted.

The Conference thus summoned at Bristol was attended by the following members of the committee, viz., Messrs. Rücker, Eschenhagen, Liznar, Mascart, Moureaux, Palazzo, Rykatcheff, A. Schmidt, C. Schott, Schuster, and various physicists and magneticians took part in some or all of the meetings, amongst whom the following may be mentioned, viz., Prof. W. G. Adams, Prof. C. Vernon Boys, Capt. Creak, Mr. W. Ellis, Prof. Carey Foster, Mr. Kitto, Dr. S. Lemström, Sir Norman Lockyer, Prof. Mathias, Dr. Privat, Dr. Snellen, Prof. H. H. Turner and Prof. Tanakdate. Dr. C. H. Lees, of the Owen's College, Manchester, and one of the secretaries of the section of mathematics and physics of the British Association, acted as secretary of the International Conference and of the Permanent Committee. The Conference was opened by an address by the President. Four meetings were held, on September 8th, 9th, 12th and 13th, at which the questions submitted to the Committee by the International Meteorological Conference were discussed, various Papers were read, and a joint meeting with the physical and engineering sections of the British Association took place, at which the effects on magnetic observatories and metallic pipes of the earth currents produced by electrical railways and tramways were discussed.

Meetings of the Permanent Committee.—During the session of the British Association the Committee also held meetings on September 7th, 9th, 12th and 13th, at which the following resolutions were unanimously approved :—

(*a.*) Matters referred to the Committee by the International Meteorological Conference. Four questions were referred to the Committee. The first of these was the following resolution of M. Dufour (Report of Paris Conference, p. 30) :—

"In calculating monthly means all days are to be taken into consideration. It is left open to each Director to give, in addition, means calculated without taking disturbed days into account." This was approved by the Committee, with the substitution of the words "it is desirable" for the words "it is left open to each Director."

The Committee were also of opinion that the quiet days chosen by the Directors of the different observatories should be communicated to the President of the Permanent Magnetic Committee, and circulated by him, and also that it is desirable to inquire if it will be possible to select the same quiet days for the different observatories.

The second resolution referred to the Committee was the following, proposed by Prof. von Bezold and M. Mascart (Report, p. 31) :—

"It is desirable to publish the monthly means of the components X, Y, Z, and at least for the months of January and July, the differences dX, dY, dZ of the hourly means from the preceding means."

In lieu of this the Committee adopted the following resolution :—

"It is desirable to publish the monthly means of the geographical components of the magnetic force for each month, and also the differences between the hourly means for each month and the monthly means for that month."

The third resolution referred to the Committee was the following, proposed by General Rykatcheff (Report, p. 32) :—

"It is desirable for the progress in terrestrial magnetism that temporary observatories should be installed in certain localities, especially in tropical countries."

On this subject, a report had been prepared at the request of the President, by Prof. von Bezold and General Rykatcheff. After considering the Report, the Committee resolved :—

"That it is desirable that temporary magnetic observatories should be established in places such as the following :—Taschkent, Peking, the Lick-Observatory, Quito, Para, Colombo, Cape of Good Hope, St. Paul or North Amsterdam, Honolulu, and Point Barrow or Sitka, or some other station in a high latitude in North America."

"That these observatories should, if possible, be provided with both absolute and variation instruments, of which the latter should be self-registering instruments, and should be established for at least seven, and, if possible, for 11 or 12 years, *i.e.*, for a complete sun spot period."

The Committee were informed by Dr. C. Schott that it was the intention of the Coast and Geodetic Survey of the United States to establish a magnetic observatory at Honolulu. In the course of the discussion on the above resolution, the Committee also resolved :—

"That it is desirable to point out that observatories at great distances from others should be provided with both absolute and self-registering variation instruments."

The fourth matter referred to the Committee was the question as to the relative advantages of long and short magnets, raised by M. Mascart at the Paris Conference (Report, p. 39). On this subject a report had been prepared, at the request of the President, by M. Mascart. After considering this report the Committee resolved :—

"Unless special reasons exist to the contrary it is desirable that the dimensions of the magnets should be as small as possible, provided that the accuracy of the results is adequately maintained."

(*b*). Resolutions passed by the Committee on matters arising during the International Conference. Prof. Eschenhagen made a statement to the Conference as to his recent investigations on minute disturbances made by very sensitive apparatus with a very open-time scale. In view of this statement, the Committee expressed their sense of the importance of the resolutions on this subject passed by the Paris Conference (Report, p. 35), and the hope that the principal observatories would carry out simultaneous observations of the character proposed.

M. Moureaux informed the Committee that preparations for such observations were already complete in the observatory at Parc St. Maur.

The Committee also passed the following resolution :—

"The Committee is of opinion that the early establishment of a magnetic observatory at the Cape of Good Hope, provided with absolute and self-registering variation instruments, would be of the highest utility to the science of terrestrial magnetism, especially in view of the antarctic expeditions which are about to leave Europe, and that the observatory should be established at such a distance from electric railways and tramways as to avoid all possibility of disturbance from them."

Directions were given that the proper steps should be taken to obtain the approval of the British Association for this resolution, with the request that, if approved, it should be forwarded to the Colonial Government.

On the motion of Prof. Adolph Schmidt, the Committee resolved :—

"That it is desirable that magnetic observations taken in regions not included in a magnetic survey should be repeated from time to time, care being taken to secure the identity of the point of observation."

* Abstract of the Report of the Permanent Committee on Terrestrial Magnetism and Atmospheric Electricity to the International Meteorological Conference.

Digitized by Google

Prof. Eschenhagen was requested to draw up a detailed scheme for the exchange between the various observatories of the curves of the self-registering variation instruments taken during important magnetic storms; and to lay the scheme before the next meeting of the Conference.

With reference to certain inquiries which Prof. Eschenhagen suggested should be addressed to the directors of magnetic observatories, the Committee was of opinion that although it would be outside the scope of their duties to make the inquiries, it was desirable that the information should be collected and published.

After the discussion on the magnetic disturbances introduced by electric railways and tramways, the following resolution was adopted by the Committee:—

"The Committee are of opinion that any sensible magnetic disturbance, produced in a magnetic observatory by electric railways or tramways, is seriously detrimental and may be fatal to the utility of the observatory. They consider that special precautions should be taken to prevent such disturbances, and append, as an example, the provisions for the protection of the Kew Observatory inserted in a bill passed by the English Parliament authorising the construction of an electric railway, the nearest point of which is to be at a distance of one kilometer from the Observatory. (Appendix II.)."

APPENDIX II.

Clause for the protection of Kew Observatory:—

1. The whole circuit used for the carrying of the current to and from the carriages in use on the railway shall consist of conductors which are insulated along the whole of their length to the satisfaction in all respects of the Commissioners of Her Majesty's Works and Public Buildings (in this section called "the Commissioners") and the said insulated conductors which convey the current to or from any of such carriages shall not at any place be separated from each other by a distance exceeding one-hundredth part of the distance of either of the conductors at that place from Kew Observatory.

2. If in the opinion of the Commissioners there are at any time reasonable grounds for assuming that by reason of the insulation or conductivity having ceased to be satisfactory a sensible magnetic field has been produced at the Observatory, the Commissioners shall have the right of testing the insulation and conductivity upon giving notice to the Company, who shall afford all necessary facilities to the engineer or officer of the Commissioners or other person appointed by them for the purpose, and the Company shall forthwith take all such steps as shall in the opinion of the Commissioners be required for preventing the production of such field.

3. The Company shall furnish to the Commissioners all necessary particulars of the method of insulation proposed to be adopted and of the distances between the conductors which carry the current to and from the carriages.

Erratum.—In the last line of the footnote on p. 7 of last week's Electricity Works Accounts (Preston), for "£15 Ordinary and Founders' shares," read "£5 Ordinary and Founders' shares."

ELECTRICITY WORKS ACCOUNTS.

Portsmouth Municipal Electric Supply Works.

Electricity supply in Portsmouth having started in operation on June 6, 1894, the accounts of the undertaking up to March 31st last cover the third completed year of working. As our analysis gives evidence of, these accounts show a very satisfactory progress so far as increase of custom goes. On the other hand, in spite of the resulting increased output, the costs have sensibly risen.

The authorised capital now stands at £142,000, and of this a total of £119,651 has been borrowed partly by the issue of Three per Cent. stock and partly by mortgages. The expended capital amounts to £112,174, representing £182 per kilowatt of capacity of generating plant installed. No additions to the mains of street lamps have been made, but through an increase of from 652 to 790 consumers the equivalent 8 c.p. lamp connection has risen some 28 per cent. viz. to 44,616. The corresponding increase in the output is 17 per cent., the units sold last year being 981,273 as compared with 839,392 for the preceding year.

An average price of 3·92d. per unit sold has been obtained, of which 1·14d. accrues from public lighting. The generating, distributing, and public lighting costs all contribute to an increase in the total costs of about 0·2d., as compared with those of 1896-7.

A working profit of £6,862 has been made which has sufficed to wipe out the previous deficit, supply £2,794 towards the redemption of debt, £3,293 interest on loans, and to leave a balance of £384 carried forward.

For the first completed year of working, viz., 1895-6, the output (in units sold) was 406,118, of which 222,398 units were sold to consumers and 183,720 for public lighting. The equivalent lamp connection at the end of the year was 29,490. The revenue was £10,103, and the expenditure £4,011.

Dundee Municipal Electric Supply Works.

Supply by the Dundee undertaking was started on March 15, 1893. The authorised capital stands at £40,000, while £41,450 has been received and £11,750 repaid. A total sum of £39,750 has been expended, representing £71 per kilowatt of plant installed. With an increase of the number of consumers from 257 to 338, an equivalent of 3,429 8 c.p. lamps have been added to the mains, representing an increase in the lamp connections of about 19 per cent. over 1896. The output has reached 323,187 units sold, being 27 per cent. higher than the corresponding value for 1896. The revenue represents an average price obtained of 4·5d. per unit.

It is satisfactory to note that the costs have been materially lowered, viz., by more than a third of a penny, and this in spite of a substantial increase in the items of rents, rates and taxes. Out of the working profit of £2,787 £700 has been paid to the sinking fund, £765 as interest on loans, and £678 repaid to the gas department.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

he Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trimblett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 98 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and wil be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

ELECTRICITY IN CIVIL ENGINEERING.

Electrical engineering receives its highest recognition at the hands of the Institution of Civil Engineers, and the electrical profession is accordingly honoured, by the election of Mr. W. H. Preece to the office of President of that Institution for the ensuing year. As the engineer-in-chief of a State department representing the most important application of electricity to the needs of civilisation, not less than as one whose personal services have done much to advance the uses of electricity in industrial and commercial life, Mr. Preece is well chosen as the representative of the electrical profession to fill that dignified and important post. The presidential address which he delivered on Tuesday evening, upon taking the chair for the first time since his election, attests the manifold and, in the majority of instances, vitally important service which electricity is playing in the direction of the great forces of nature for the use and convenience of man. Itself a "force of nature" that is but little in evidence as a commercially available quantity, it nevertheless serves better than any other of nature's forces the purpose of modifying and directing the energy in nature so that it shall benefit mankind. The address was also, to a large extent, an apology for the State control of the telegraph service of the United Kingdom, and an attempt to show that "the jealousy and contempt so freely displayed for Government work are not justified by results." Mr. Preece believes "it is the fashion to decry the public service," but hopes that his successors will drive home the nail he desires to insert "in the coffin of the traditional general and false belief in the inefficiency of a great and growing public service." A man of many parts, versatile and imaginative, Mr. Preece naturally led his hearers along a large number of paths of electrical engineering, and breathed a breath of life upon the dry bones of manifold statistics and hard technical facts. Passing briefly in review the early part of his address, which deals with the progress of the Institution during the forty years of his membership, we may note that in that period the roll of the Institution has swelled from 894 to 7,088 members; and, at the present time, 71 per cent. are home members, 21 per cent. colonial members, and

Digitized by Google

8 per cent. foreign members. An important departure made by the Council of the Institution, comparatively recently, is next commented upon, viz., the system of election by examination which it imposes upon the rank and file of the candidates seeking admission to the Institution. We invite attention to the numbers showing the large percentages of "passes," an indication that the system is working satisfactorily. The popularity of the new measure is shown by the entrance of 71 candidates for the examination last month. Naturally, the subject of engineering examinations leads Mr. PREECE to the kindred topic of Technical Education. Upon this subject, he has some trenchant observations to make. Technical education may be all very well, he implies, but it is possible to do mischief by having the wrong sort of technical education. "We are suffering," he asserts, "from a lack of competent teachers"—a pronunciamento which is followed by a sarcastic diatribe against "the ideal professor of abstract science," who, we are told, "is a very arrogant and dogmatic individual, and, being a sort of little monarch in his own laboratory and lecture-room, surrounded by devoted subjects, his word is law, and he regards the world at large, especially the practical world, as outside his domain and beneath his notice. He is generally behind the age." There are many professors, we think, who do not come up to this "ideal," but who have conferred upon practical engineering many a valuable service, by virtue of their knowledge of the bearing of theory upon practice. Such men are the LODGE and HEAVISIDE and CROOKES of to day, and the FARADAY and DAVY of yesterday.

We now come to the second and major portion of Mr. PREECE'S address, namely, the series of reviews of the progress and present position of the various branches of civil engineering which are associated with the applications of electricity. Telegraphy naturally occupies the premier position. An interesting table shows the extent of the system of British telegraphs, in which there are 485,000 miles of wire belonging to the Post Office and its licencees out of a total of 1,111,866 miles. The crying need for a serviceable insulation compound, to enable wires to be placed undeground, is touched upon; and in this connection the announcement is made that "the cable companies are contemplating leading their long cables from Cornwall up to London" by the same method as that being employed by Mr. PREECE on the 76 conductor buried cable under construction between London and Birmingham, viz., lead-covered paper cables. Under the heading "Railways" Mr. PREECE gives a mass of handy statistical information regarding the extent to which various systems and descriptions of instruments are in use. Telephony also receives due recognition, and to Mr. PREECE, as, indeed, to every Government official, telephony is only a branch of telegraphy. "Telephony," he says, "is an Imperial business, like the post and the telegraph"—a declaration to which we have always subscribed our complete assent. But let it be worked on truly imperial lines, and not for party purposes or in the furtherance of crude socialistic theories. The "assumed bad bargain" in absorbing the telegraphs in 1869 is held to be a deterrent to the absorption of the telephones in the present year of grace. Mr. PREECE makes short work of the assumption, and shows that the present magnificent system of telegraphs has been built virtually out of revenue, and, if now bought out by a syndicate, could be valued at over £30,000,000. The purchase of the "business of the telegraph companies" in 1869 is stated to have been made for £4,989,048; but this is evidently not the whole sum paid and appears to exclude the purchase of plant and other stock. Mr. PREECE, however, is justified by facts in his assertion that "there has been no failure and there was no bad bargain"—and the moral ought to be pointed in the direction of State telephony, which, but for the parsimony in the Treasury of years ago, would long have been *un fait accompli*. Referring, by-the-way, to the same subject of State telephony is an article we publish this week in a later column. Space does not permit of our dealing with the other sections of Mr. PREECE'S address; nor, although these will be read with deep interest, do they call for especial comment. In the address, regarded as a whole, we are presented with a well-instructed and judicial survey of the relation of electricity to civil engineering at the present day.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

A New Magneto-Optic Effect.—D. Macaluso and O. M. Corbino have made the following discovery: A beam of sunlight polarised by a Nicol traverses the magnetic field furnished by a Ruhmkorff electromagnet, and then a second Nicol and a cylindrical lens, finally impinging upon a concave Rowland grating. After introducing between the poles a Bunsen flame with a sodium bead, the two D lines are observed, and they are produced in such a manner that D_2 has a breadth of about a quarter of the distance between them. If, under these conditions, the current is made, bands parallel to the lines are seen on each side of them. From a careful observation of these bands, and their movement on turning the analyser, it is found that they are due to light polarised in various planes, or, more precisely, that the plane of polarisation has undergone, during the passage of the light across the sodium vapour in the magnetic field, a rotation which increases continuously from the outside to the edge of the line. This rotation, which begins to show itself for the line D_2 at a distance more than two-thirds of the interval between the two lines, increases rapidly as the edge is approached, eventually becoming something like 270deg. When the line is broadened, the relative rotation of the outlying portions diminishes, and the bands also broaden out. Examining with Babinet's compensator or a quarter-wave plate, it is found that circularly polarised light is followed by elliptically polarised light in which the ratio of the two axes tends rapidly towards zero. As the lines are broadened, the circularly polarised light disappears completely and the elliptical polarisation is confined to the edges. Similar phenomena, but less pronounced, are obtained with a lithium salt. The explanation must be sought in an inequality of speed of propagation and of absorption of the two circular components of the original radiation under the influence of a magnetic field.

[MACALUSO and CORBINO, *Comptes Rendus*, No. 17, 1898.]

Mutual Influence of Cathode Surfaces.—D. F. Tollenaer endeavours to explain all the phenomena observed by Wiedemann with regard to complex cathodes on the emission theory. Wiedemann introduces a new kind of *horror vacui* by his thesis that cathode rays are incapable of penetrating the dark cathode space of a neighbouring cathode, and cites an experiment in which he mounted a card spread with chalk in the right angle between two cathodes in contact, thus obtaining two dark spaces showing a kind of mutual repulsion. Tollenaer traces out the probable paths of the cathode projectiles and shows that they do penetrate both dark spaces, but are deflected owing to a modification of the field by the vicinity of the other cathode.

[TOLLENAER, *Wied. Ann.*, No. 9, 1898.]

Difference between Röntgen and Cathode Rays.—The argument for the essential identity of cathode and Röntgen rays is based upon the fact that there are various kinds of cathode rays, which, as regards deflectibility and penetrating power, may be arranged in a continuous series. In this series the Röntgen rays obtain an extreme place at the end, where the deflectibility is zero and the absorption by solids a minimum. A

Digitized by Google

difficulty occurs at once, through the fact of luminous rays being undeflected and Hertzian waves being unabsorbed under somewhat similar circumstances, which makes the classification of Röntgen rays among cathode rays appear artificial. J. Von Geitler attempts to bring out clearly the essential difference between the two classes of rays by a study of their electrification or ionisation properties. He quotes a number of experiments to show that Röntgen rays are absolutely incapable of conveying a charge. They can equalise opposite charges, by rendering the air between them conducting, but they cannot, like cathode rays, convey an electric charge into the interior of a closed metallic vessel connected to earth, or out of such a vessel into the open air. All this speaks in favour of regarding the Röntgen rays as essentially different from cathode rays, and this desideratum is fulfilled by both the new theories of Röntgen rays now before the public, the English wave theory, in which cathode particles when stopped generate single-wave impulses, and the Dutch corpuscular theory which regards Röntgen rays as discharged cathode particles.

[GEITLER, *Wied. Ann.*, No. 9, 1898.]

Magnetic Iron Ore.—It is interesting to know that certain specimens of magnetite surpass most kinds of steel in their capacity of retaining magnetism. A. Abt has tested specimens of magnetite from Moravicza, in Siebenbürgen. They have a greater degree of remanent magnetism than steel manufactured by the puddling, Bessemer, or Martin processes. But they are surpassed in this respect by certain crucible steels and by tungsten steel, a Westphalian specimen of the latter showing a remanent magnetic moment of 62 units, as against 37 for "diamond steel," 34 for Reschicza crucible steel, 29 for Martin steel, 15 for puddling steel, and only 3 for Bessemer steel. In 122 days a rod of magnetite only lost 1·5 per cent. of its remanent magnetism.

[ABT, *Wied. Ann.*, No. 9, 1898.]

Coherers.—Our knowledge of the nature of coherer actions is not enlarged by the work of E. Aschkinass, but he provides a store of additional material from which to frame the true theory. Without endorsing Branly's view, Aschkinass ventures to advance some important criticisms of the view held by Lodge and his followers, that minute sparks accompanying the coherer action weld the particles together, or form temporary metallic bridges between them. In the first place, that view would not account for the anomalous behaviour of PbO_2 powder, whose resistance is greatly *increased* by the influence of electric radiation, or of copper sulphide, which reacts in a similar way, but not so strongly. Further, when the air is exhausted from a coherer tube to such an extent that all spark discharges cease to pass, its sensitive reaction takes place as before, though the spark explanation hardly holds good. It might be suggested that some temporary chemical action takes place. But this is rendered improbable by the fact that peroxide of lead reacts in the anomalous manner referred to on the slightest provocation, but does not indicate any breaking up into the monoxide or sesquioxide even after prolonged action. And in spite of the observations of Dorn, the author found that good coherers could be made of the noble metals by a somewhat prolonged shaking up. Also, when the surface of copper was chemically cleaned by exposing to a red heat and subsequent plunging into methyl alcohol, the coherer action was as good as ever. The only advantage of a skin of oxide is that the pressure under which the particles are packed may be varied within wider limits. Another item which lacks explanation up to the present is the efficacy of gentle heat in restoring the original resistance. A mere expansion would have just the opposite effect. Neither can a chemical instability of the reduced resistance be called into play, for even a hot coherer acts perfectly. As long as the heating is going on, the coherer will be "self-righting" without concussion—a fact which might be of commercial value. Further, in a complete theory of the coherer the effect of sound waves must find its due place. Lodge's theory, so far the most successful, is probably only a rough approximation to the truth.

[ASCHKINASS, *Wied. Ann.*; No. 10, 1898.]

Duration of Röntgen Ray Emission.—Roiti, Trouton and Colardeau have by various means endeavoured to ascertain the duration of a single X-ray impulse. The values arrived at varied from $\frac{1}{100}$th to $\frac{1}{10000}$th of a second. H. Morize has devised and carried out a method of determining this duration, which he believes to be capable of great accuracy. A photographic plate is fixed on the end of the shaft of a high-speed motor. A metallic slit is mounted in a radial direction just in front of the plate. Photographs are taken when the motor is at rest and when it is moving at a known speed. The images of the slit appear drawn out sideways when the plate moves, and the amount of the broadening is a measure of the duration of the X-ray impulse. The results obtained by this method show that to each current impulse in the primary of the induction coil there correspond several successive impulses of the rays. Successive images of decreasing intensity are thus produced, separated by uniform intervals. On some plates four images can be traced, the last being very feeble. The durations obtained ranged from 65 to 107 millionths of a second, with a mean of 82×10^{-6}. The intervals were 0·00033sec. on the average.

[MORIZE, *Comptes Rendus*, Oct. 17, 1898.]

THE STATE AND THE TELEPHONES.

The Blue Book just issued, containing a verbatim report of the evidence given and copies of documents laid before the Select Parliamentary Committee on Telephones, enables us to recall attention to some of the leading incidents of the inquiry and to the changes of policy, and even of administration, foreshadowed therein. Adopting an intelligent view of its "Reference," which really begged the whole question, the Committee set itself to inquire, Whether the telephone service is now or is calculated to become of general benefit? secondly, Is the Post Office hindered by legal agreement or by good faith from competing itself or through licencees with the National Telephone Co. in exchange areas? lastly, Ought competition to take place, and should municipal or other local authorities be empowered to undertake a telephone service; and if so, on what terms? We have said that the terms of Reference begged the question by virtually assuming that the telephone service may become "of such general benefit" as to justify its being undertaken by local authorities. Many of the members, including the chairman, proceeded on this assumption throughout, their line of cross-examination being directed mainly to elicit evidence that the system is not of general utility now, and that it would be so if local bodies took it in hand. Of course, there was no lack of witnesses representing, directly or indirectly, the two or three municipalities who are prime movers in this inquiry; but their testimony was challenged in every particular by experienced officials, not only of the offending Company but by the permanent and Parliamentary representatives of the Post Office. As to inefficiency, the chief complaint came from Glasgow, where admittedly the Company have been wilfully obstructed by the Corporation; and as regards other charges, they were either disproved altogether, or shown to be ancient history. Even as regards high rentals, the comparisons sought to be made between this and other countries turned out to be fallacious, or were vitiated by circumstances over which neither the Company nor the Post Office has any control, the Treasury alone being responsible. The same explanation was given of the comparative unpopularity of the telephone in these islands—that is to say, of its not being popularly used by the general public, like the telegraphs—the fact being that the Post Office is forbidden to canvass for custom, whilst the Company is bound to work its business as a paying concern. The Treasury is alike answerable for the prohibition, and, primarily, for the telephone business being vested in the hands of private monopolists, with whom the Post Office is not permitted to effectively compete or allow anybody else to compete, for fear of damaging its own sources of revenue. These facts came out early in the inquiry, together with the further facts that successive Postmaster-

Digitized by Google

Generals, Secretaries and Chancellors of the Exchequer had, after due experience of competition, expressed themselves emphatically against it in the interests of the public. These views were shared by the Post Office officials, who, while declaring their ability to compete if given a free hand, strongly deprecated it in any shape or form under present conditions, and especially in view of the short period which has to elapse before the State must perforce, as they contend, take the telephone business into its own hands. The Treasury itself was cognisant of these views, and gave expression to similar opinions of its own, though always safeguarding itself by jealously retaining the legal right to compete if the necessity arose—a right which its licensee, the Telephone Company, has never disputed. Its chairman had frequent interviews with the high officials we have named; and notably during negotiations, which lasted from 1892 to 1896 with reference to the acquisition of the company's trunk lines by the Government, the policy of the Department and of the Treasury was fully disclosed and discussed by all the parties—the company endeavouring on its part to get these views of policy embodied in the documents, the Department on its side declining to do more than give verbal assurances, fearing to part with its last remaining weapon of control, namely, the right to compete, or issue competing licences, if the company misbehaved itself.

It is important to bear these facts in mind when considering the line taken up with regard to them by the Committee. The facts could not be gainsaid; how were they to be made of non-effect? One course remained for the Committee if it meant to disregard the assurances of the higher officials and pin them to the legal wording of the documents to which they had put their signatures; and this was to attack the permanent responsible officials of the Post Office. No one present at the enquiry, or who has read the hostile and we may almost say vindictive cross-examination to which those officers were subjected, can fail to see the unfairness of the whole proceeding. Mr. Preece was a very strong witness, his bluff and outspoken declarations provoking a good deal of irritation and futile criticism on the part of his inexpert and ill-informed questioners, who, when they could do nothing better, endeavoured to cast discredit on his estimates, or fasten upon him the responsibilities which had been proved, over and over again, to rest with the Government. In this respect the evidence of Mr. Preece was in entire agreement with that of Mr. Lamb and others, as to the uphill work created for them by the Government, first in granting competing licences without due regard to the Post Office rights, and afterwards by restricting its powers of effective control by competition on business lines. Mr. Lamb, who fared much worse even than the Engineer-in-Chief, put in a document which it may be well to reproduce here, bearing, as it does, upon this material point. It is part of a letter from the Treasury, signed by Mr, Courtney as long ago as 1883, and which has been operative ever since :—

800. . . . "In reply to these arguments my Lords have to observe that they find no evidence that the extension of the business is necessary in order to maintain the profit on the capital already sunk in it. It is new profit, therefore, not the maintenance of the old, which has to be weighed against the general objection to the appearance of the State as a competitor in trade. The sound principle, in the opinion of my Lords, is that the State, as regards all functions which are not by their nature exclusively its own, should at most be ready to supplement, not endeavour to supersede private enterprise, and that a rough, but not inaccurate test of the legitimacy of its procedure is not to act in anticipation of possible demand. My Lords do not propose to push this doctrine so far as to exclude declarations in Parliament, the affixing of notices in Post Offices, and such like means of showing what business you are ready to undertake; but they object to anything in the nature of solicitation, and above all of personal solicitation. For these reasons they are not prepared to approve of the appointment of travelling clerks." Then they go on: "For all these reasons, my Lords do not wish you to do more, in respect of exchanges and private wires, than to bring your offers fairly within the knowledge of the public, and to wait for their demands upon you."

801. Do you know whether that was the Treasury minute that induced Mr. Fawcett, who was then Postmaster-General, to encourage free competition between the companies?—I do not think it was.

802. Was not it the fact that he not being able to carry on the telephone service on behalf of the Postmaster-General in the same way as a private firm would carry it on, he decided to throw the whole thing open to competition?—I think that that letter had its influence, but I do not think that that letter stood alone.

This explains the failure of Departmental competition; and it did not take many years of unlimited competition, outside, to show that the whole system was becoming chaotic and dangerous to public interests. One of the principal competitors gradually absorbed all the rest; and there is evidence to show that this process was countenanced and even encouraged, not by the Post Office alone but by the Treasury, with the obvious aim of more efficiently serving the general public, rendering the control more manageable, and the prospective transfer to the State more easy. The Post Office, in the first instance, appears to have signed away its exclusive rights in the telephone most reluctantly, but being compelled to do so, it made, as Mr. Lamb said, the best of a bad job, always working in harmony with Treasury instructions. These instructions have gradually resulted in the amalgamation of all the companies, the creation of a virtual monopoly in the National Telephone Co., and finally the acquisition of its trunk lines by the State. All this in pursuance of a distinct policy, clearly defined, though slow in operation, openly avowed and freely discussed by all the parties concerned. The Company has, therefore, become sole agent for, or virtual partner with, the Post Office, so far at least as the Exchange areas are concerned, with rights reserved by the Post Office to compete on good reason being shown. Needless to say, no reason has been shown since the negotiations, which began in 1892, and which in their very nature constituted a working agreement between the two contracting parties. Our surprise at the suggestion that one of the parties should now be asked to authorise competitors against the other party would be very great indeed, were it not for the still more surprising manner in which those who make the suggestion have treated the secretary of the Post Office charged with the conduct of those negotiations. Mr. Lamb has been intimately associated with the administration of the telegraphs ever since their transfer to the State, and on the death of Mr. Patey, succeeded him as head of the Telegraph and Telephone Departments. Upon him, therefore, the Committee appear to have thrown the blame of everything not to their liking, in respect of the Department's present relations with the National Telephone Co. To begin with, he was accused of being party to the initialling of the heads of an important agreement with the Company on the eve of Sir James Fergusson's retirement, the insinuation being that the transaction was rushed through to avoid its being upset by his successor. It turned out to be merely the completion of old negotiations, which, amongst other business, it was right and proper should be disposed of by the Postmaster-General who had dealt with them. Mr. Arnold Morley, his successor, not only approved these heads of agreement but handed over the delimitation of areas provisionally arranged therein to Mr. Lamb's discretion, a discretion which he continued to exercise without fresh authority from Mr. Morley's successor, but which the Committee treated as having no authority at all, although shown to be in conformity with official usage. A Treasury Minute quoted by Sir Jas. Fergusson, dated 1892, clearly indicates the policy at that time.

2,248. . . . "As to fresh licences, no further licence for the whole country will be granted; and even for a licence to establish an exchange in a particular town, no application will be entertained unless a formal resolution in its favour has been passed by the Corporation, or other municipal authority, and evidence given that there is sufficient capital subscribed to carry out the undertaking. In this way competition will not be excluded, but a check will be imposed on the formation of companies whose sole object is to force the existing licensees to buy them up."

The drift of this is to put an end to competition, and it is plain that the idea of municipalities themselves competing had not then been thought of; consequently, no steps had ever been taken to facilitate such competition. For this the Committee thought fit to implicitly condemn Mr. Lamb, just as if the objections which are inherent to all schemes of telephonic competition whatsoever were of his creation.

Coming now to the year 1893, one or two powerful municipalities commenced an agitation for telephonic service in their own hands; and the National Telephone Co., who were then negotiating the transfer of their trunk lines, at once wrote to the Post Office expressing alarm, and suggesting preventive measures. The following is an extract from the

Digitized by Google

famous letter of February 9, 1898, arising out of an application from the Glasgow Town Council:—

8,596. . . . "With the trunk wires connecting town and town in the hands of the Company, the Company have no reason to apprehend danger but with such trunk wires in the hands of the Government the very existence of the Company is threatened, should it be the policy of the Department either to favour the municipalisation of the local service, or to give way to that policy under Parliamentary pressure. You may say, and with perfect truth, that the *status quo* has undergone no change since the time when the heads of arrangement were signed by Sir James Fergusson and Mr. Forbes, but there is an essential difference between possibilities and probabilities, and as it has now been brought home to us that the condition of affairs which I have indicated is within the range of practical politics, I venture to think that it is the duty of the Board of Directors of this Company to ascertain the views and policy of the Department, and to safeguard the interests of their shareholders in the pending arrangements before it is too late, and they have parted from their great source of strength, viz., the trunk lines. There are two ways of dealing with the matter: (1) The constitution of large areas comprising within them all the towns surrounding each great centre with which such towns have community of interest, *e.g.*, take the case of Manchester. The Company have constituted Manchester and each of the following towns surrounding it, viz., Bolton, Bury, Rochdale, Oldham, Ashton, Stockport, and Glossop, separate areas. All these places centre upon Manchester, and have close business relations with it, and if they were all put together into one area the Company would have the protection which they have now, and to which they are entitled, because the inter-communication between those towns being in the hands of the Company there would be no inducement on the part of the separate municipalities to set up separate systems. It is true that the constitution of large areas such as I have indicated would trench upon the Post Office revenue, but that might be met by providing for an adequate payment by the Company to the Department. (2) The insertion in the agreement now in negotiation between the Department and the Company of provisions rendering it impracticable for the Department to grant licences to municipal or other local authorities. I would venture to point out that there is nothing in the Treasury minute of last session inconsistent with the insertion of such provisions."

To these suggestions the Postmaster-General, in a letter dated March 13, 1898, and signed by Mr. Lamb, gave a courteous but flat refusal, and there the matter ended. The correspondence was duly submitted to the Treasury; but it does not appear to have been brought specially to the notice of the present Chief Secretary of the Post Office or the present Postmaster-General. This correspondence is referred to in the Report as "the two remarkable letters"; and the Chairman's cross-examination was directed to show that Mr. Lamb had secreted these letters away from his chiefs, and that, notwithstanding the refusal to enlarge the areas, he had in reality enlarged them in the interests of the Company. Hours were spent in badgering the witness on these grave points, and it was not until nearly the end of the proceedings that he was permitted to explain the wide distinction between the large areas asked for and the grouped local areas actually granted:—

Chairman.

8,878. "The question of large areas is, of course, a question of degree; what one person might think a large area another might think a small area. The principle involved, as I understand it, in the Company's suggestion was, for instance, that there should be no two towns in one area?—No, sir. The Company mentioned in their letter eight areas which were to be grouped in one district, and each of those eight areas already included more than one town, and the suggestion was that instead of areas based on the principles which had been agreed upon with the Treasury, they should have great districts of country combining areas of that kind; and that suggestion was never accepted, and was never acted upon."

8,879. "I may be wrong, but is not the principle at the bottom of the suggestion of the Company that large areas would interfere with municipal licences; thus, that if you had two municipalities within one area, it would be difficult to get either of those municipalities to agree to be under the jurisdiction of the other for telephone purposes?—No, sir; it was admitted from the earliest days that there ought to be and would be cases in which two or more towns would be grouped together; but what was denied the Company in this case was the amalgamation of a series of areas of that kind into one district."

This explanation, however, not fitting in with the fixed ideas of the Committee, was treated as meaningless, and the history of the "two remarkable letters" pursued with a persistency and ascerbity which could bear but one interpretation, namely, a set determination to make the Secretary for the Telegraphs the scapegoat for the sins of the Government, past and present. That he will be cast out into the wilderness we find it hard to believe, though there are sinister rumours afloat as to his being superseded. But whatever happens, the candid reader of this Blue Book will perceive that a Parliamentary Committee is imbued with party spirit as strongly as Parliament itself, and that it is not exactly a tribunal where questions of personal rectitude or official fidelity can be tried with judicial fairness.

A NEW PATTERN OF PREECE-TROTTER PHOTOMETER.

A new form of illumination photometer, on the Preece-Trotter principle, has been brought out by Messrs. Nalder Bros. and Co. While said to give results of equal accuracy with those of the old pattern, it has the advantage of less than half the weight and bulk, and what is even more important, its cost is also considerably less than the original Preece-Trotter instrument. In place of an incandescent lamp and accumulator, an amyl-acetate lamp is employed. Fig. 1

FIG. 1.—General View of Illumination Photometer.

is a general view of the instrument, and Fig. 2 is a sectional elevation showing the construction. The height of the lamp A is adjusted by screwing the lamp-holder in or out until the top of the flame just touches the point of a bent arm (not shown in the figure), as observed in the mirror M. The cap covering the paper screen S is then removed, and the photometer is set so that the screen is horizontal. There is a slit T in the screen through which the inside screen R is seen, and

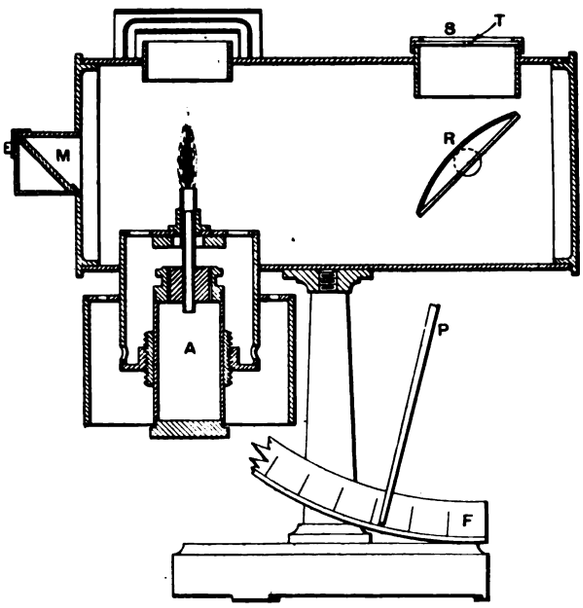

FIG. 2.—Sectional Elevation of Instrument.

the illumination of the slit is balanced to equal that of the upper screen by turning R by means of the arm P. A pointer is attached to this arm, and indicates on the scale F the illumination directly in candle-feet. The inside screen has a slightly bluish tint to remove the colour difficulty to some extent. A convenient case is supplied for containing the instrument, fitted with an oil can and scissors for trimming the lamp, and very explicit instructions for use are issued with each photometer.

MR. W. H. PREECE'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF CIVIL ENGINEERS.*

The election to the position of President is the highest possible reward which the Institution can give to those who have endeavoured to serve it well and truly. I have often feared that my position as a specialist might have proved a bar to the attainment of my greatest ambition. It has come at last. I am also proud, not alone for the sake of that branch of the profession to which I specially belong, but also because I am a member of the great Civil Service of this country. Twenty-eight of my 46 years of professional work have been spent in the service of the Crown. The jealousy and contempt so freely displayed for Government work are not justified by results. It is the fashion to decry the public service, My successors will be able to drive home the nail I desire to insert in the coffin of the traditional general and false belief in the inefficiency of a great and growing public service.

Examinations.

Our great European rivals relegate the examination and selection of their engineers to their Governments, but we, under the guidance of our immediate Past-President, have taken this load on our own shoulders ; not before it was needed, for the competition of highly educated engineers of other countries was becoming rather too evident. Loss of business is a potent force to effect reform. The reform itself in our case has materially strengthened the credentials of our Institution. Our task has been a difficult one, for, while we recognise most fully that the practical training of the drawing-office, of the shop and of works in progress are the true school for the engineer, we cannot help thinking that he ought to acquire that knowledge which is the basis of his profession and those exact methods of inquiry and of thought which lead to truthful deduction and to sound judgment, before he can satisfactorily begin his professional experience. The foundation of engineering is science. Science is not only a knowledge of the facts of nature, but of the development of her laws. It is, in the language of Huxley, organised common sense. The man who determines to practise in the business of applying those facts and laws to add to the comfort and happiness of mankind must know something of the mental tools and weapons that mathematics and logic have placed at his disposal. His mind must be trained to habits of inquiry, and he should know something of the experience and teaching of the past. Hence the Institution, as the tutelary genius of the profession, has established a system of qualifying, not competing, examinations for admission into its ranks ; not only to test the education and preparation of those who wish to recruit our numbers, and the qulaifications of those who desire to improve their position in our classes, but also to enhance the standing of the modern engineer as the most scientific and advanced of all the learned professions. The result of the first examinations has been highly satisfactory. Out of 24 examined for studentship, three only failed to pass. Of 40 examined for Associate Membership, seven failed. Of 48 theses submitted in lieu of examination, five only failed to secure a satisfactory report. The popularity of the measure among even the examinees is shown by the entrance of 71 for this last October examination. The examination papers which have been set are by no means of an insignificant character, yet 86 per cent. of marks have been acquired on the whole examination.

Technical Education.

There is a fashion in Great Britain for technical education just now. Enormous sums of money are being annually spent on secondary, intermediate, and more advanced education. It is well that it is so. It is well that the country has awakened from its conservatism and apathy, and that it is putting its schools in order. But is it doing so on a true issue, and are we distributing our money through the right channels? Our trade is suffering even in our own colonies from the competition of our continental neighbours, who are said to be beating us by their technically superior hand labour. It is true we are suffering, but is this the true cause? It is rather from the superior commercial skill of the principals at home and the accomplished polyglot and well-trained traveller abroad, as well as from a financial system that is more moral and more sound than that rampant in England through the gross abuses of the Limited Liability Act of 1862. Our law courts are almost daily the scenes of the exposure of the modern spoiling of the Egyptians. A new industry is designed by some simple, well-devised, and economical process. Capital is required to develop it. In Germany, financial support is readily subscribed by the generous and enlightened policy of its banks. In England we require a syndicate, a pioneer company, and finally an appeal to the public for an enlarged limited company. The financiers, the lawyers, the brokers, as well as the original inventor, have to be satisfied, and this satisfaction grows very much with the state of the money market and the excitement for investment with the public. The industry is established, but with a terribly overloaded capital—overloaded by the harpies who have sprung from the operations of the Limited Liability Act. The same industry could be established in Germany with probably half the capital. Its manufacture would be supervised there with greater skill, and it would be developed as a business by better trained agents. We are thus fairly beaten on our own commercial preserves. Our educational methods have begun at the wrong end. We ought to teach the masters first and then the men. Moreover, we have to teach the teachers and those who have control of the purse-strings. The County Councils of England are scarcely qualified as yet to discharge the very serious duty of properly dealing with a question so few of them understand—though many of them have tackled the matter manfully, especially the London County Council, through its Technical Education Board, on which a large proportion of co-opted experts have seats, who, by supporting existing institutions, have contributed towards the supply of teachers. But how are we to approach the masters? A fault once discovered is half-way to repair. It is difficult to remove the scales from the eyes of the man who has been successful in business and who knows not of his blindness ; but the coming generation will be more enlightened, and the future masters better educated. We are suffering from a lack of competent teachers. A teacher who has had no training in the practical world is worse than useless, for he imparts ideas derived from his inner consciousness or from the false teaching of his own abstract professor, which lead to mischief. In my own experience I have met with very serious inconveniences from this cause. The ideal professor of pure abstract science is a very charming personage, but he is a very arrogant and dogmatic individual, and, being a sort of little monarch in his own laboratory and lecture-room, surrounded by his devoted subjects, his word is law, and he regards the world at large, especially the practical world, as outside his domain and beneath his notice. He is generally behind the age. These are not the men for technical institutes. Such teachers should possess the diploma of this Institution.

Telegraphy.

The extent of the present system of British telegraphs is shown by the following table :—

	Miles of wire.
General Post Office and its licensees	435,000
Railway companies	105,000
India and Colonies	387,966
Submarine cables	183,400
Total	1,111,366

The form of submarine cable and the nature of the materials used in its construction have varied but very little since the first cable was laid in 1851. The recent invasion of our channels and seas by the *Limnoria terebrans*, a mischievous little crustacean which bores through the gutta-percha insulating covering, and exposes the copper conductor to the sea-water, leading to its certain destruction, has led to the use of a serving of brass tape as a defence. It has proved most effective. No one has done more than Lord Kelvin to improve the working of submarine cables. His recording apparatus is almost universally employed on long cables. The number of electrical impulses which can be sent through any cable per minute is dependent upon its form, and is subject to simple and exact laws, but it varies with the quality and purity of the materials used. There is no difficulty in maintaining the purity of copper. The purity of gutta-percha is, however, questionable. The supply of this dielectric has dwindled ; it has failed to meet the demand ; its cultivation has been neglected. The result is a dearth of the commodity, a great increase in price, and its adulteration by spurious gums. India-rubber, its sole competitor for cables, is being absorbed for waterproof garments and pneumatic tyres, but for underground purposes paper is being used to an enormous extent. Paper has the merit, when kept dry, not only of being an admirable insulator, but of being very durable. There is paper in existence in our libraries over 1,000 years old. The difficulty is to keep it dry. This is one of the problems the engineer delights to consider. He has been most successful in obtaining a solution. The lead-covered paper cables, which are being laid in the streets of all our great cities, are admirable. I am laying one of 76 wires for the Post Office telegraphs between London and Birmingham, and the cable companies are contemplating leading their long cables from Cornwall up to London, so as to be free from the weather troubles of this wet and stormy island.

It is impossible to forecast the future of telegraphy. The introduction of the telephone is revolutionising the mode of transacting business. There seems to be a distinct want of some instrument to record the fleeting words and figures of bargains and orders transmitted by telephone. Hence a supplement to that marvellous machine is needed. The telautograph and electrical type-writer will fill this want. Visions of dispensing with wires altogether

*Abstract of an Address delivered by Mr. W. H. Preece, C.B., F.R.S., on November 1, 1898.

Digitized by Google

have been fostered by the popularity of Marconi's "wireless telegraphy"; but wireless telegraphy is as old as telegraphy itself, and a practical system of my own is now in actual use by the Post Office and the War Department. Sensational experiments for booming a new financial enterprise are not processes that commend themselves to the Institution. We want practical work and engineering progress.

Telephony.

I was sent, in 1877, together with Sir Henry Fischer, to investigate the telegraph system of the American Continent, and especially to inquire into the accuracy of the incredible report that a young Scotchman named Bell had succeeded in transmitting the human voice along wires to great distances by electricity. I returned from the States with the first pair of practical instruments that reached this country. They differed but little from the instrument that is used to-day to receive the sounds. The receiver, the part of the telephone that converts the energy of electric currents into sounds that reproduce speech, sprang nearly perfect in all its beauty and startling effect, from the hands of Graham Bell. But the transmitting portion, that part which transforms the energy of the human voice into electric currents, has constantly been improved since Edison and Hughes showed us how to use the varying resistance of carbon in a loose condition, subject to change of pressure and of motion under the influence of sonorous vibrations. The third portion, the circuit, is that to the improvement of which I have devoted my special attention. Speech is now practically possible between any two post-offices in the United Kingdom. We can also speak between many important towns in England and in France. It is theoretically possible to talk with every capital in Europe, and we are now considering the submersion of special telephone cables to Belgium, Holland and Germany. The progress of the use of the telephone in Great Britain has been checked by financial complications. It fell into the hands of the company promoter. It has remained the shuttlecock of the Stock Exchange. It is the function of the Postmaster-General to work for the public every system of inter-communication of thought which affects the interests of the whole nation. Telephony is an imperial business, like the post and the telegraph. It ought to be in the hands of the State. The public and the press have frequently kicked violently against the present régime. Committees of Parliament have sat and deliberated upon the question. The report of the last committee is now under consideration.

"*Quidquid delirant reges, plectuntur Achivi.*"

Two causes exist to impede this desirable absorption, the fear of being "done" by watered and inflated capital, and the assumed bad bargain made in absorbing the telegraphs in 1869. The former is a mere bugbear. The public does not want to purchase stock. It wants to acquire a plant and business which can be easily and fairly valued. The latter is a gross fallacy. The business of the telegraph companies—practically an unlimited monopoly—was purchased on absolutely fair terms, viz., 20 years' purchase of the net profits. The sum paid was £4,989,048. The number of messages then sent in one year was about 5,000,000, and the gross income about £500,000. The income has now grown to £3,071,723, the number of messages has reached 83,029,999, and the capital account which was closed in 1891, viz., £10,131,129, including the cost of the Post Office extensions, remained the same. If a syndicate desired now to repurchase the business and acquire the plant, they would have to find a capital of over £30,000,000. In what respect, then, was the transfer of the telegraphs to the State a failure? Our magnificent system has been built virtually out of revenue, our tariff is very cheap, scarcely a village of any consequence is without its telegraph, our Press is virtually subsidised by having its news supplied at much less than cost price; we can rely upon safe and accurate delivery, and upon speedy despatch of messages. We lead the world. There has been no failure, and there was no bad bargain. The present condition of the telephone business in this country is shown by the following return:—

Telephones in use.

National Telephone Co. (June 30, 1898)	.....	133,498
General Post Office	ditto	9,588
Railway Companies	ditto	8,933
Total	.....	152,019

Railways.

The regulation of the traffic on a railway, and the general business of the line, could not possibly be conducted without the telegraph. The safety of the passenger and the freedom from collision are due to the introduction of the block system, which is worked entirely by electric signals, and which has been made compulsory by Parliament on all British railways. The employment of electricity in the working of railways has not only been highly beneficent in the security of human life, but it has vastly increased the capacity of a road to carry trains. The underground traffic of the metropolis is conducted with marvellous regularity and security, though the trains are burrowing about in darkness and following each other with such short intervals of time, that the limit of the line for the number of trains has been reached. Electric traction is going to extend this limit by increasing the acceleration at starting and improving the speed of running. It will also reduce the cost of working per train-mile, so that the advent of electricity as a moving agency is certain to prove highly economical. What it will do as a remover of bad smells and foul air and for personal comfort cannot be estimated. Time alone will enable us to assess the intrinsic value of public satisfaction acquired by the change. The extent to which electrical appliances are used on the railways of this country is shown by the following tables. Table I. gives the length of double and single line in the United Kingdom open for passenger traffic on December 31, 1895, the latest period for which returns have been published, and the length of such lines worked upon the various systems:—

—	Line open for passenger traffic.		Worked on absolute-block system.				Worked on other telegraph systems.		Single lines worked under.		
				Single line.							
	Double.	Single.	Double line.	Combined with train-staff system.	Without train-staff system.	By electrically-controlled train-staff or tablet.	Double line.	Single line.	Single-engine system.	Train-porter system.	Train-staff system.

Table II. gives the number and description of the various classes of electrical apparatus in use on railways in the United Kingdom in the year 1898:—

Single needle	13,494	Galvanometers	390
Morse sounders	431	Large trembler bells (platform, &c.)	2,063
Morse recorders	105		
Telephones	12,043	Small trembler bells	5,913
Duplex apparatus (complete)	26	Night and day switches	4,527
Bell instruments (for message work, complete, with keys, relay & galvanometers, &c.)	425	Fire-alarm commutators	96
		Train describers	1,122
		Light indicators	1,100
Phonopores (complete)	110	Signal repeater disks	924
Block instruments	27,146	Test-boxes	27
Train staff instruments	673	Water-tank apparatus	13
Tyer's tablet instruments	1,137	Telephone switchboards	17
Interlocking instruments	4,275	Bell indicators	86
Repeater instruments	18,450	Point detector	1
Treadles	1,658	Signal lever lock	230
Fouling bars	452	Extra contact-markers and switches	539
Fouling bar indicators	224		
Replacers	31	Magneto-electric bells	4
Slot selectors	368		
Single-stroke and relay bells	18,447	Total	115,247

Electric Light.

But it is in supplying us with light, without defiling the air we breathe in our dwellings with noxious vapour, that electricity has proved to be a true benefactor to the human race. The Legislature has facilitated the acquisition by municipalities of those local industries that affect the welfare of the whole community, such as road-making, sewerage, the supply of water, tramways, and, above all, electric light. No one doubts that new industries of a speculative character are best pioneered by private enterprise. The company promoter, has, however, so abused the power placed in his hands by the Limited Liability Act that, not only has the development of electric lighting been retarded in this country, but the prospects of private enterprise in furthering other industries has been checked. Fortunately the success, the comfort, the intrinsic value, the economy and the sanitary properties of electric light have commended it to our municipal magnates, and its introduction has become the fashion. The table on the opposite page shows the position of the industry in this country and in the United States at the present time.

In spite of our financial troubles, of the inertia of municipal bodies, of the active competition of vested interests, our progress compares not unfavourably with other European countries, but the progress of the industry in the United States has been phenomenal. The return for the United Kingdom is, however, by no means complete. It omits all private installations. We in the Post Office alone have 50,000 lamps which are not enumerated;

and if we consider all our great railway companies, banks, warehouses, manufactories, and shops which have their own installations, the statistics will be very considerably extended. Lamps are being improved and cheapened, wiring is being reduced in cost, and the economic distribution of energy is being furthered. But the most promising field for economy is the combination of all classes of electrical industry in one centre, especially that of light and tramway working where fuel is cheap, water abundant for condensing, and nuisances of no account. The cost of the production of electrical energy depends principally upon the continuity of its output. If it can be generated continuously during the 24 hours of the day its cost is only a fraction of a penny per unit. If it is used solely for light, a unit may cost threepence. Hence local authorities, who are undertakers of electric energy, neglect their duty to those who have elected them as the custodians of their interests if they fail to secure the tramways in their district, either as their own property or as customers for their current. For the tramways, by taking energy during the day, reduce the cost of working during the night by removing the incubus of running continuously imposed on undertakers by Act of Parliament. This may enable the ratepayers to be supplied at a price for electric light certainly one penny per unit less than if there were no tramways. The cheaper the supply of energy per unit the more certain and speedy the advent of the electric light as the poor man's lamp, and the more beneficial its introduction into the confined, ill-ventilated and overcrowded homes of the working classes.

It is on board ship that electric light has been pre-eminently successful, and where it filled such a crying want that its introduction met with no check. It was almost immediately and universally adopted. Search lights, prompted by the great development of the torpedo, were introduced into our Navy as early as 1875 by Mr. Henry Wilde. The first ship to be fitted with internal electric lighting was the "Inflexible" in 1882. In 1884 the Admiralty ordered it to be applied to all H.M. warships. The first application of electrical power was in the case of H.M.S. "Barfleur," where motors were used for working guns and for the supply of ammunition. It has subsequently been partially extended to the working of gun-turrets, ventilating fans, capstans, and boat-hoisting gear; but hydraulics, the child of our venerable Past-President, Lord Armstrong, is the form still more generally preferred and used for power in our Navy, though other nations make a much more extended use of electricity. The technical reports received by the United States Navy Department indicate that the electrical appliances on their warships worked very successfully during the recent war. Electrical conductors are readily stowed away in safe quarters, and easily repaired when severed by shot. The electrical energy used in a first-class battleship is expended thus :—

Internal lighting	60	E.H.P.
Search-lights	65	"
Ventilation	30	"
Capstans, hoists, &c.	60	"
Reserve	45	"
Total	260	"
Number of glow-lamps	1,000	
" " search-lamps	6	
" " ventilating fans	16	
" " motors	2 to 8	

The following table illustrates the progress of electric work done by that branch of the service which is so eminently presided over by our Vice-President, Sir W. H. White :—

Year.	Ships fitted with electricity.		Total number fitted.		Electric machinery.	
	Search lights.	Internal lighting.	Search lights.	Internal lighting. Number of lamps.	Number of sets fitted.	Total E.H.P.
1876	Nil	Nil	Nil	Nil	Nil	Nil
1876 to 1880 ...	19	Nil	38	Nil	19	33
1880 " 1884 ...	30	1	50	...	30	120
1884 " 1888 ...	150	30	220	8,000	180	3,700
1888 " 1894 ...	265	126	750	50,000	450	15,000
1894 " 1898 ...	500	240	1,100	95,000	800	25,000

(To be concluded.)

PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society, on October 28th, Mr. Shelford Bidwell, president, in the chair, a Paper was read by Mr. W. R. PIDGEON on

"An Influence Machine."

The machine, which was exhibited, consists of a pair of glass discs, rotating in opposite directions upon a spindle. They are partially covered on one face with narrow radial sectors of tinfoil, each provided with a small brass knob. This face of the disc, including its sectors, is then coated with insulating wax, leaving only the knobs projecting through the wax. Two earthing brushes pass through two insulated fixed inductors, and support them. The inductors are kept charged by exploring-points connected to each, and placed so as to collect electricity from the revolving discs. By means of brushes, the sectors on each of the discs are successively earthed at the moment they pass the fixed inductors, *i.e.*, at the moment that their capacity is a maximum; and they are made to deliver up their charge to the main collecting brushes at the moment when they are electrically farthest from the inductors, *i.e.*, when their capacity is a minimum. Hence, if there is no loss of electricity in the process, the potential at the collecting brushes is proportionately high. Each sector of a particular disc, as it moves away from its inductor with rising potential, induces a corresponding potential on the sectors opposed to it on the second disc; this action is cumulative. The thick coating of wax restricts leakage to the small area of the contact knobs, so that surface effects of dirt and moisture are minimised.

Capt. J. H. THOMSON, R.E., said that, apart from its electrical merits, the machine possessed advantages in mechanical construction. He thought there was still room for improvement in this respect. The countershaft should be done away with, and ball-bearings should be introduced. The inductor was a distinct improvement; he thought the efficiency might be increased by adding other inductors. Platinum-iridium was the best material for brushes of such machines.

Prof. AYRTON asked what efficiency was obtained with modern influence machines, in general.

Capt. THOMSON had found that when running a machine by a motor, about 80 per cent. of the power was wasted in mechanical friction, and of the remaining 20 per cent. a great deal was lost as electrical leakage.

Dr. S. P. THOMPSON thought it had been pointed out by Mr. Wimshurst that influence machines did not work well unless there were at least two thicknesses of glass between the inducing and induced conductors. That was why Mr. Wimshurst put his sectors on the outer faces of the glass disc. Mr. Pidgeon had departed from this. The advantage of the narrow spacing of the sectors was not very apparent.

Mr. WIMSHURST (abstract of communication): Waxing the discs reduces leakage, and increases the output; the wax-coating virtually doubles the number of plates. Inductors contribute a further increase to the output. In 1883, Mr. Wimshurst tried thick coatings of shellac, and also, duplicating the glass, with, in some cases, sectors upon the second glass to increase the capacity. The output was increased, but the construction lost simplicity. The indifference of Mr. Pidgeon's machine to dirt and dust was a most valuable result.

Mr. PIDGEON, in reply, showed a set of secondary inductors such as Capt. Thomson had just proposed. They improved the output by about 15 per cent., but they were troublesome to keep in order, for they increased the tendency to "reverse."

Dr. S. P. THOMPSON then repeated an experiment discovered by Prof. Righi, on

"A Magneto-Optic Phenomenon."

It was originally described in *Roma, R. Accad. Lincei, Atti.* 7, *ser.* 5, 1898. A substance absorptive of light is submitted to a powerful magnetic field between the pole-pieces of an electromagnet. The pole-pieces are drilled so that a beam of light from an arc-lamp can traverse the gap *along* the magnetic lines. A polarising prism is placed between the arc-lamp and the electromagnet. After having passed through the magnetising apparatus, the beam thus polarised is examined by an analyser. The analyser must be turned to "extinction" before the magnetising current is turned on. If this is done, brightness is restored at the analyser as soon as the magnetic field is established. The substance absorbing the light in the gap may be nitric oxide fumes, or an ordinary spirit-lamp sodium flame. The second effect to be noticed is that when the emergent beam is examined, there is a splitting of the lines. Righi explains this by supposing that when light of frequency n is brought into a magnetic field and passed *along* the lines of the field, it is split up into two sets of circular waves, a right-handed and a left-handed set, one of which sets is accelerated and the other retarded. There are now two frequencies, n_1, n_2, one a little higher and the other a little lower than n. But since the analyser is adjusted to extinguish n there is brightness for n_1, n_2. Normally, nitric oxide absorbs green and red is observed, but when the magnetic field is set up, blue-green light is seen at the analyser, for there are now two different kinds of light being absorbed, one of higher and one of lower frequency than the normal, and what is observed is the complementary spectrum. Again, if a tube of sodium is warmed

Digitized by Google

to a point far short of that which would cause it to emit visible rays, and the vapour is passed into the magnet gap at the moment when the magnetic field is set up, the D line becomes visible in the observing spectroscope, *i.e.*, the emission spectrum is obtained of a substance which is not actually emitting light.

Mr. BLAKESLEY said that no doubt the analyser was used at the position of extinction for convenience merely. In other positions the eye would be overwhelmed with light.

Mr. ALBERT CAMPBELL then read a Paper on

"The Magnetic Fluxes in Meters and other Electrical Instruments."

He has recently undertaken the measurement of the magnetic fluxes and fields in certain instruments, to determine the order of magnitude of the flux density. In other cases the *total* flux is measured; and in the tests on meters the power lost in the various parts of the instruments is determined. For the measurement of B, the ordinary ballistic-galvanometer method is employed, with an exploring coil. But, for alternating fluxes, two special methods are adopted, in the first of which the exploring coil is in series with a heating-coil associated with a thermopile; in the second, a telephone is connected in series with the search-coil and a potentiometer resistance strip. A constant current is sent through the strip from the main alternate-current circuit supplying the meter or other apparatus; the telephone and search-coil, therefore, forms a shunt to that circuit at the strip. The search coil is put into position in the field to be tested, and the strip is then adjusted to give silence in the telephone. All these methods are described in detail in the Paper, and very important deductions are made, especially as regards the influence of the earth's field on instruments generally assumed to be independent of the earth's H. In a few cases, diagrams are given of the fluxes in magnets, showing exactly what proportion of the total flux is effective at the gap.

Dr. S. P. THOMPSON suggested that as the Paper was of great significance to all who were interested in the design of electric meters and other measuring instruments involving a knowledge of magnetic fluxes and their variation, an opportunity should be given for a full discussion.

The PRESIDENT proposed votes of thanks, and adjourned the discussion of Mr. Campbell's Paper to the next meeting on November 11th.

ELECTRICITY IN MOROCCO.

In the course of a recent visit to Gibraltar, we found it a subject of general remark that, while the residents of the Rock still languish for the supply of electric current for both public and private use, the old-world city of Tangier "on the other side of the water" had been for years lighted electrically. However, Gibraltar will soon have its electricity supply, and in a form greatly in advance of anything to be found in Barbary. The particulars of the lighting at Tangier are not without interest. The first installation was started in November 1891, and, except for a short period in 1892, when considerable modifications were made in the plant and cables, the advance of electric lighting in public favour has gradually increased. The Moors have now begun to lose their old antipathy to anything that marks Christian progress in their country, and are gradually having the electric light installed in their houses. The wires are now drawn all over the antique quarter behind the telegraph station, and branches are gradually being carried into the Moorish quarter—that part of the town where neither Europeans nor Jews are allowed to reside. Even the tiny Moorish shops (more like cupboards than places of business) in the main streets are beginning to be wired for the electric light. The Moorish Minister for Foreign Affairs has the light installed in his offices, but, so far, the Moorish Governor (or Pacha) stands aloof. Visitors for the first time to Tangier are naturally surprised to see this old world Moorish town lighted by electricity. Others, who return to visit the place after a lengthy absence, express the view that the quaint city is being spoiled, but these same visitors, when making a call or visiting the outskirts by night, must appreciate the vast improvement that is to be recorded. Nearly all the chief residences of the legations, the hotels (and many of these are large and well managed establishments), offices and shops are lighted electrically. There are 100 public and 1,500 private incandescent lights in use. The street lighting would be on a much more general scale but for the absence of any properly-constituted municipal body to regulate the lighting and to collect the necessary rates for covering the cost. The existing local Commission of Hygiene has no power to force house or property owners to pay rates, and in the government of the country no municipal body exists for such a purpose. Many of the chief residents, however, subscribe to a fund for lighting the immediate vicinity of their properties, and amongst these may be mentioned the Eastern Telegraph Company, which pays for the lighting by electricity of the approach to the station and offices. Little or no interruption has occurred in the lighting from the start. The plant consists of two Pieper continuous current dynamos, supplied by the Allgemeine Elektricitäts Gesellschaft of Berlin and one Helvetia-Alioth machine—the former of 120 volts 300 amperes, the latter 120 volts 242 amperes. The former machines are driven direct by two 60 H.P. Willans engines and the latter direct by a 55 H.P. Carels engine. One 40 H.P. and one 60 H.P. Babcock-Willcox boilers and one 120 H.P. boiler by De Naeyer and Co. are included in the plant. The lighting is almost entirely incandescent, except that a few 250-c.p. enclosed arcs are sometimes employed for the theatre lighting. The cables are all overhead, and, except for a small portion of the work, are covered. The works are owned by the Compania Transatlantica of Barcelona, and are ably managed by the general manager of the Company, Don Mariano Viado, and the electrical engineer, Don Jose Canales.

Well to the fore in electric lighting, Tangier has also had for many years a public and private telephone service. This was established in 1881 by its present proprietor, Don Emilio Rotondo Nicolau. For some time only a very few subscribers were obtained, but the number has now reached 140, and is slowly increasing. Public telephones have been established at the customs house, on the pier, &c., and these instruments are free to subscribers. The installation extends to Mount Washington (about four miles on the road to Cape Spartel), where the representatives of foreign States and many of the chief citizens have their summer residences. The telephone subscription is 120 pesetas (about 65s.) per annum for one instrument, and 180 pesetas for two.

Electricity is gradually extending its popularity to other places in Morocco, and, though at present only Tangier has local telegraphic communication, a central telephone service has recently been established at Casablanca, a port about 160 miles south of Tangier, and has at present rather more than 30 subscribers.

CORRESPONDENCE.

THE BREAKDOWN AT BRIGHTON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your issue of Oct. 28 some editorial notes on the above subject, which conclude by offering a suggestion for avoiding a repetition of this unfortunate occurrence. You suggest the temporary expedient (for it can be no other) of pinning up the minimum cut-outs and inserting maximum cut-outs in the shape of fuses. Now, I venture to submit that this would not overcome the difficulty, and that if an armature were to "short-circuit" under these conditions, the result would be precisely the same, viz., a complete cessation of supply.

To make myself clear, I must refer to the explanation you offer as to the dropping out of all the cut-outs, it being that the combined effect of decreased speed and armature reaction reduced the dynamo fields to zero. This is undoubtedly the correct explanation, and is a perfectly well-known result on the short-circuiting of a shunt dynamo.

From this it must be perfectly clear that the falling of the minimum cut-outs was the *result* and not the *cause* of the cessation of current, and that, therefore, the pinning up of those cut-outs would not have saved the station from a "shut-down."

It appears to me that there is a definite and very serious danger introduced by the adoption of this method. Suppose that a bad "short" occurs somewhere on the network or feeders, instead of on an armature (which can be quickly disconnected), and that it "shuts down" the station. The engineer finds himself in the extremely awkward predicament of being unable to locate the "short," without current on the mains, and at the same time unable to "re-start" to obtain the necessary current.

The only conclusion that I can come to in considering the foregoing is that the use of "non-return cut-outs" and "separate excitation" are not only possible remedies, but are *absolutely essential* and afford *complete* security against the class of breakdown under consideration.—Yours, &c.,

Nov. 1, 1898. WM. C. P. TAPPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Is it not possible that a break in the shunt circuit of the damaged dynamo at Brighton may have occurred, and that this will, therefore, account for the general breakdown?

Digitized by Google

Such a break may have occurred either accidentally or it may have been done intentionally in order to prevent the short-circuited armature from completely burning out, and this if done too rapidly would produce an effect analogous to an accidental breakage of the shunt, that is a sudden rise of voltage at the end of the broken shunt coil which was originally at the lower potential, and would therefore tend to reverse or would at any rate weaken for an instant the shunt currents in all the other machines in parallel.

I should imagine that if all instruments which could be damaged by a sudden and short rise of potential were removed from the bars, a test as to whether this was really the case or not could be made during light load upon two or three of the machines without much danger of damage.—Yours, &c.,

Bristol, Nov. 2, 1898. ARNOLD PHILIP.

FOREIGN-MADE APPARATUS IN GOVERNMENT AND MUNICIPAL CONTRACTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We ask for permission to call attention through your columns to a disadvantage, under which we as English inventors and manufacturers in England of electricity meters, suffer, in having to compete with foreign meters made abroad with all the advantages of long hours and low wages.

Notwithstanding the fact that Parliament has decided that in all Government contracts there shall be a clause, that where practicable all goods supplied under them shall be of British manufacture, and that this clause has been adopted by a majority of municipal corporations, yet there still remains a number of municipal contracts under which foreign-made meters are not excluded though the English manufacturer is additionally handicapped by the requirement that for all his goods the trades union hours and wages shall be followed, thus leaving, so far as price and profit are concerned, a still greater advantage in the hands of the foreigner.

We think it is only necessary to call attention to the matter for municipal authorities and consulting engineers to bring their tender forms into line with those of the Government, for it is a recognised principle, at least as regards goods paid for with public money, that the competition of cheap foreign labour should not be encouraged. It must be understood that we do not at all object to the competition in meters of foreign inventors, we only ask that their inventions, if sold in England, should be made in England, and should thus contribute, as ours do, to the support and encouragement of native industry and to the relief of our municipal rates and Imperial taxes.—Yours, &c.,

ARTHUR CHAMBERLAIN, Director.
(For Chamberlain and Hookham, Limited.)

Birmingham, Nov. 1, 1898.

SHOREDITCH DUST DESTRUCTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: No one wishes for the success of the utilisation of towns' refuse for the generation of electricity more than myself; but let us not be led away by random generalisations and data unsupported by facts as to works costs, and inasmuch as the published accounts of the Vestry must be assumed to be correct, I await the promised figures for the year's working; although if the "initial expenditure that would not recur" were credited against the loss as stated, the true working results would be apparent and Mr. Kershaw and Dr. Mansfield Robinson have evidently missed this salient fact in their respective replies to my previous communication; but the aforesaid gentlemen having imported into the controversy deliberate personalities, such as "virgin experimentalist," "amateur adventurer," and being guilty of "school-boy carelessness," these epithets call for some contradiction by me. I now give the facts that did occur.

In June, 1893, I was requested by the Vestry Clerk, being a ratepayer, to give him some idea of how and at what cost I would propose to light the Shoreditch area. I did so, and handed him a report as a ratepayer, which I understood was of some value at this initial stage. In November, 1893, I was employed and received payment for a design and scheme to bring in the then idle large property in Ivy-street for the purposes of a similar scheme with baths and washhouses as now erected. In 1894 a representative of the contractors and designers of the present destructor called on me, and asked if I would grant my patent rights to them for the Shoreditch schemes and "row in their boat," which on the terms mentioned I refused. In 1895, upon the request for competing schemes by the Shoreditch Vestry, I designed the special scheme, according to my patents, that was submitted by the eminent firm of Messrs. Daniel Adamson and Co., who were lowest in price and whose guaranteed cost for labour for 20,000 tons of refuse per annum was £1,100, and I beg to subjoin Messrs. Kincaid, Waller and Manville's report thereon to the Shoreditch Vestry:—

MESSRS. DANIEL ADAMSON AND COMPANY, OF DUKINFIELD.

This firm is one of the highest reputation in the manufacture of steam-raising apparatus, and they have submitted a scheme which in many respects is different from the majority of those placed before you, and for which, if erected in accordance with the specification issued by you, the cost will amount to £14,400. They propose to supply only 10 cells in place of 12, but these cells will be of larger area than the 12 stipulated for, and will, therefore, burn the requisite amount of refuse daily. The refuse furnaces, in place of being ranged alongside the boilers, are placed, as in Messrs. Fraser and Sons' scheme, under the boilers. This likewise involves the clinkering floor being somewhat enclosed, since a second floor in addition to the tipping floor is provided opposite each row of furnaces, from which the boilers will be fired by coal so far as that is required, and on which also the refuse may be screened to separate some of the cinder from it, should you adopt that portion of their scheme. The destructor furnaces are of a type that would enable the perfect combustion of the refuse and its gases to be relied upon, and the furnaces provided by them are arranged to both feed and clinker automatically.

The amount of coal this firm considers necessary to obtain the necessary evaporation is extremely high, namely, three tons per day. We think, however, that this is probably only due to the fact that, as they have not heretofore erected a dust destructor, they have probably not attached sufficient importance to the calorific value of the refuse to be dealt with, and in any case the arrangement of their boilers and furnaces is such that the same evaporation could be relied upon as that suggested by other tenderers. They also estimate the cost of labour in working the plant at £1,100 per annum, but they do not make any statement as to the amount required to maintain the apparatus, merely stating that this would be very low.

The scheme put forward is an extremely well-worked-out one, and considering the extra amount of work in the erection of the two extra floors which are included in their tender, is not by any means a dear one. They make an alternative tender at £13,150 if double-flued tubular boilers are provided by them in place of the water-tube boilers, and we have no objections to offer to this alternative should you be prepared to consider their tender for recommendation. They also quote as extras for a screen and apparatus in connection therewith, and for other sundries, which you would probably not be prepared to consider at the present moment.

The Society of Engineers in 1894 awarded me their gold medal for my Paper on "Utilisation of Towns' Refuse for Generating Steam."

Further comment is needless.—Yours, &c.,

T. W. BAKER.

7, Broad-street House, E.C., Nov. 1, 1898.

[This correspondence is now closed.—ED. *E.*]

ELECTRIC CANAL HAULAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his Paper on electric haulage, which you reprinted in your last issue, Mr. A. H. Allen mentions the system I installed in 1893 on the Burgundy Canal, at Pouilly, and he says that this system could not be suitable for general canal navigation. Mr. A. H. Allen recalls also American attempts, none of which have attained any degree of success. These statements of Mr. A. H. Allen are misleading, as your readers would conclude from them that the question of electric haulage on canals is still now in the same state of affairs as it was after the attempts of the American engineers and after my installation on the Burgundy Canal in 1893.

When working my system at Pouilly I soon realised that, although it was well adapted for the case, there were difficulties in the way of its general adoption, and I began to study new systems with a view to haul separately each barge, one after the other. I gave a first intimation about these systems to the International Congress on Navigation held in La Hague in August, 1894; but, at that time, my studies were not yet completed. First experiments took place in 1894 and 1895 on the Burgundy Canal, at Dijon, and these having resulted

Digitized by Google

in a decided success, a company patented the devices and asked from the Government powers to work the system on the canals from Aire to the river Escaut, in the north of France.

The authorities wishing to have a full, practical experiment of the system before granting this licence, bade the company first to work only 26 kilometres, extending from Aire to Pont à Vendin, on the Aire and Deule Canals. This installation was completed in the beginning of 1898, and immediately set into operation. M. La Rivière, Ingénieur-en-Chef des Ponts et Chaussées, in Lille, who is in charge of these canals, gave a full account of the results to the International Congress on Navigation, held last August at Brussels. Those who are interested in electric haulage will find an exhaustive specification of the system in his Paper read before the Congress.

The system consists of tricycles running on the tow-paths and fitted with electric motors, which receive the current through overhead conductors and trolleys. We have now in operation two generating stations, each of a capacity of 200 H.P.; they suffice to work 26 kilometres of canal. These stations are distant by 13 kilometres from one another; they generate continuous current, transmitted through wires supported on wooden poles alongside the tow-path. The system dispenses with any aërial or other railway, thus minimising the capital spent on construction.

The only objectionable feature of the scheme is the running of the tricycles on the common tow-path, as it seems it should result in a very low efficiency; but tests have shown that, on very common roads, the total efficiency of a tricycle, viz., the quotient of the power received at the brushes of the motor by the power available on the tow-rope, averages 60 per cent.

The motors are 6 B.H.P. dynamos, made by the St. Alsacienne, of Belfort. This power is necessary to haul over 300-ton barges at the rate of 1½ miles per hour. The assumption by Mr. A. H. Allen that a power of 2 B.H.P. could haul 100 tons at the speed of 2½ miles per hour does not agree with my own experience, nor with the experiments carried out on different French canals by M. de Mas, Ingénieur-en-Chef des Ponts and Chaussées, in Paris, who summed up his tests in a Paper read before the Congress in Brussels last August. In our canals and with our barges, a power of 2 B.H.P. per 100 tons of cargo does not result in a greater speed than 1½ miles per hour.

The Aire and Deule Canal carries a very heavy traffic; barges follow each other at 290 to 300 metres from one another, and the number of barges passing through the section now in operation averages over 17,000 every year. The traffic entrusted to the Company has been very feeble in the beginning, owing to the opposition they met with from the horse-owners and bargemen; but it is rapidly increasing, and they hope it will increase still more rapidly when they have completed their installation up to the river Escaut. As the system has proved successful, the company have been authorised to extend their lines over 84 kilometres, from Aire to the river Escaut; a new section of 30 kilometres is now being constructed, and the complement will soon follow.

They haul gratis all empty barges, and charge 1 franc per kilometre barge carrying 290 to 300 tons, the ordinary load on this canal. This fare corresponds to $\frac{10\text{d.} \times 1{\cdot}6}{300}$, say 0·053d. per ton mile. Though not cheaper than horse traction, electric haulage begins to be a favourite with bargemen, because of its superior speed and regularity, and the company are confident they will soon carry on the whole traffic.

I refrain from calculating the profit when such is the state of affairs; this calculation, as it has not been ascertained by practice, would be liable to the same objections and doubts as those given by Mr. A. H. Allen in his Paper. Nevertheless, as the through traffic averages 17,000 barges every year, and the total capital, including reserve fund, is 3,400,000fr., this profit cannot fail to be very large.

I wonder whether the Allen system would prove adequate in the conditions just referred to, and whether it would be possible to erect an aërial railway to resist the weight and tractive force of the locomotives which are necessary on this navigation. But I do not intend to criticise the very interesting system devised by Mr. A. H. Allen, which may attain success on English waterways. I only wished to mention what I have done since my installation on the Burgundy Canal, at Pouilly, to which Mr. A. H. Allen has alluded, and to give, respecting the present state of the question, some information which I supposed would be welcome to engineers dealing with inland navigation and with electricity.—Yours, &c.,

F. GALLIOT,
Ingénieur-en-Chef des Ponts et Chaussées à Dijon.

Dijon, France, Oct. 26, 1898.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October 14, 1898.*

An Arc Light Regulator Without a Clutch.—An extremely simple arc light controlling mechanism has just been patented by Mr. Sigmund Bergmann, of this city. The armature or plunger of the controlling solenoid which is in series with the arc travels through the full range of carbon consumption, the plunger being rigidly attached to the carbon. To obtain a uniform vertical lift (equal to the weight of the holder and upper carbon) through the entire travel of the plunger, the solenoid is wound with an increasing number of layers towards its upper and particularly towards its lower end. The pole of a uniformly wound solenoid on a core equal to or greater than the solenoid in length is, as is well known, a maximum when one end of the core is about in a mid-position within the solenoid. By increasing the number of turns towards the ends of the solenoid the pull of the ends of the core near either end of the coil is increased, and a practical uniformity of pull obtained over a considerable travel. In the lamp described, the upper end of the hollow spool on which the core is wound is sealed, and the core fitting tightly within the spool acts as the plunger of its own dashpot. The spool is of metal, and the tightly fitting core always serves as a contact for the current. The series resistance is wound in a helical coil wrapped in an annular chamber around the controlling solenoid.

An Electrically-Driven Turntable.—The Erie Railroad Co. has just put into operation in its Jersey City yards a turntable which is operated by an electric motor. The two longitudinal girders supporting the table platform are pivoted on 7½in. shafts, each girder carrying its own bearings. The girders rest upon an equalising drum, and the entire weight rests on a set of rollers, as in drawbridge practice. In laying out the electrical application the problem to be solved was to keep the motor in a fixed position relative to the gears, so that their alignment would be unaffected by any tilting end motion of the table caused by the weight of the locomotive passing on to the platform. To effect this the motor is set on a circular base between the girders, and is thus independent of any vertical motion of the ends of the table. The power is communicated by a double reduction system of gearing from a 13 H.P. series-wound motor installed with its armature and shaft in a vertical position. The turntable is double-ended, each end being equipped with a controller with a reversing mechanism. When an engine has been turned the operator walks back to the other end of the table and operates it from that end, thus saving the power that would otherwise be necessary to turn the table back. The wires are brought from a near-by pole underground, through a cast-iron pipe to the centre of the table, where they are brought up through the vertical steel tube forming the central pivot. By means of copper collector rings at the top of the tube connection is maintained with the motors and controllers. Proper protective devices, switches, &c., are placed in a box on the pole referred to. The amount of power required to turn the table through an arc of 180deg. is very small. In practice it is cut off when the table has moved over an arc of about 85deg., the momentum then acquired sufficing to carry it around through the remaining degrees of a semi-circle. The

Digitized by Google

motion of the table as it approaches the stopping point is retarded by a hand-brake acting on the friction wheel. The turntable is moved over an arc of 180deg. in about one half a minute, and engines are turned about with practically no delay. Prior to the installation of this table it was almost impossible to avoid an accumulation of engines on the adjacent tracks. It is estimated that this turntable will effect a saving of $270 a month in its operation as compared with a hand-turned table. The electrical equipment was furnished by the General Electric Co.

October 21st, 1898.

Electrical Decorations.—On the occasion of the conclave at Pittsburg of the Knights-Templar, October 11th-14th, the electrical decorations were probably the most elaborate and extensive ever attempted. The main feature was a series of metal skeleton arches, 29 in number, spanning Fifth-avenue in Pittsburg and its extension into Allegheny. Over 7,000 50-volt lamps were used in the work. The current was supplied by the large central station of the Allegheny County Light Co. Each arch was supplied with current by a specially installed transformer, that for the quadruple arches being of 875-lights capacity and for the single arch of 150-lights capacity. The number of lights varied from 125 to 165 on the single arches and from 350 16 c.p. lamps to 450 of 10 c.p. on the quadruple arches. Besides these arches, there were many elaborate private display signs, the total additional load on the station due to the conclave being estimated at about 3,500 H.P., making the evening peak of the combined arc and incandescent service in the Company's two stations almost 9,000 H.P. A triumphal arch, erected by the city in front of the building occupied by the Department of Public Safety, was illuminated by 1,685 incandescent lights, supplied with current from the isolated plant of the adjacent building. Among the electrical signs may be mentioned a cross, 110ft. in height and 60ft. in width over all, the trunk and arms being 12ft. wide, and the whole illuminated with 300 incandescent lights. Letters ran down the upright and across the arms of the cross, which was outlined with a double row of 688 red lamps, the letters being composed of 2,300 frosted white lamps.

A New Telephone Exchange.—The New York Telephone Co. is now erecting in Harlem, in the upper part of Manhattan Borough (old New York City), a new exchange which will embody all of the latest improvements in practical telephony. The new multiple board being installed will have a capacity of about 1,500 lines, and will be fitted throughout with visual signals and all the latest improvements. This will be the first board erected in this city on the common battery system.

A New Telephone Company.—New York city would seem to offer a particularly inviting field for telephone competition, but hitherto nothing in this direction has been attempted. During the past week, however, a company has been organised in this city to establish a telephone system in competition with the strongly intrenched New York Telephone Co., which represents the Bell interests. The new Company is developing plans rather quietly, and not much has been given out for public information. Some well-known business men are said to be at the back of the enterprise. The Company has a capital stock of £1,000,000, and it has been given out that it intends to make a charge for unlimited service in Manhattan Borough of £20 per year, against £48 charged by the Bell Company, and will grant besides several privileges and concessions not enjoyed by the patrons of the old company. The new Company proposes to develop a field that has hitherto been untouched, namely, securing subscribers among families living in apartment houses. To these patrons the Company promises to give unlimited service for 4s. a month on group lines. The new Company claims to have all the needed rights to engage in active business, but just how it came into possession of these rights has not yet been divulged. It claims that it can serve 40,000 subscribers with its capital.

LEGAL INTELLIGENCE.

Cambridge Electric Supply Co. (Limited) v. The Cambridge Union.

The hearing of this appeal against the assessment for rating purposes of the Cambridge Electric Supply Co. was resumed in the Outer Temple, London, on the 29th ult. We have received the following brief report of the proceedings:—

Mr. RAWLINSON, Q.C., opened the case for the respondents.

Mr. W. G. COOKE, rating surveyor, stated that he considered the life of electric lighting machinery was at least 40 years, and that a sum representing four-ninths of 1 per cent. annually was a reasonable and sufficient amount to allow for depreciation. This length of life and depreciation would apply to all classes of machinery. Respecting cables, he looked upon them as if they were a pane of glass, and if they broke down they would need to be wholly renewed out of revenue, as they could not be repaired. Under these circumstances nothing should be allowed for depreciation.

Mr. BARNETT, engineering valuer, stated that he had examined the works, and considered 20 years was a reasonable life, but his opinions differed from Mr. Cooke. He thought £300 per annum, or two-thirds of 1 per cent., was ample depreciation on a capital of £45,000. He had seen the company's works, and thought there were not £500 worth of spare plant, cables, or material on the premises. Asked if he was aware that there were at least 12 drums of cable in stock on the day of his visit worth from £40 to £50 apiece, representing more than the sum he stated, he said he had not seen them. He also considered that a hypothetical tenant should be quite satisfied after paying £2,100 rent if he made £500 a year profit.

Mr. A. H. PREECE was asked what he considered a fair life for electricity undertakings, and he thought about 25 years. Asked did he consider Lancashire boilers at 200lb. pressure would last that time, he said he considered they would. India-rubber cables he gave a life of at least 15 years, and transformers up to 100 years. It was pointed out that companies, such as the Westminster Electric Supply Corporation, allowed 3½ per cent. on their capital for depreciation, although they had no rubber mains, and that Manchester and other large towns allowed more. He agreed with the previous witness that £300 was quite enough for depreciation on £45,000.

Mr. RAWLINSON addressed the Recorder on behalf of the Respondents, and Mr. RYDE replied for the company.

The learned Recorder reserved his decision, and promised to deliver judgment on Dec. 1.

Everard v. Higgs.

This case came before Mr. Justice Wright and a jury on Friday last, and was an action brought by Mr. F. E. Everard, electrical engineer, against Mr. J. Limbrey Higgs, solicitor, to recover £60 in respect of certain shares. It appeared that plaintiff purchased a patent for an electrical accumulator, and formed the I.E.S. Accumulator Co. to work it. Plaintiff had 100 shares in the company, and in March, 1896, the defendant informed him that he had arranged to sell 10,000 or 20,000 shares, and as he had not that number, he asked plaintiff to transfer his 100 shares, and promised to pay him the amount realised by their sale when he received the money. Plaintiff transferred his shares, and subsequently heard that there had been a pooling arrangement. He asked the defendant for the money which the shares had realised, and the defendant alleged that the plaintiff was a member of the pool, and would have to take his share of the pooling arrangement, which would entitle him to 60 vendors' shares, 17 out of 5,000 new shares purchased out of the proceeds of the pool and £1. 13s. 4d. in cash. Eventually the plaintiff agreed to accept this, but the defendant failed to take any steps to transfer the shares until after proceedings for the winding-up of the company had been instituted. He now submitted that he was entitled to stand by his original arrangement to receive the price realised by the sale of the shares, 12s. each. Defendant said he offered, and plaintiff agreed to accept, the vendors' shares and the new shares in satisfaction of his claim. These had been tendered, but had not been accepted.

The jury gave a verdict for the plaintiff for £50, and judgment was entered accordingly.

Defendant's counsel asked for a stay of execution for 10 days, which was granted.

Howell v. Howell's Simplex Anti-Inductive Telephone Syndicate (Limited).

In the City of London Court last week, before Mr. G. Pitt-Lewis, Thomas J. Howell, described as an inventor, sought to recover £8, two weeks' salary, due from the defendants. Plaintiff's case was that the company employed him as their electrical engineer at £4 per week. Defendants said they had never taken any step by which they had become liable to pay the plaintiff the salary claimed. As a matter of fact the plaintiff was in the service of a Mr. Macintosh, and defendants never adopted the contract. Judgment for plaintiff, with costs.

Wilson v. Easton, Anderson and Goolden (Limited).

On the application of a debenture-holder for £69,000 of an issue of £180,000 debentures, on the 28th ult., Mr. Justice Romer appointed Mr. W. B. Peat as receiver and manager of the defendant company. Mr. Ralph Neville, Q.C., said the company was in a difficult position, mainly in consequence of an arrangement for purchase by the Hooley Syndicate having fallen through. It had on its books contracts to the amount of

Digitized by Google

£120,000, including installations of the electric light, and many of these contracts were nearly completed. His lordship authorised Mr. Peat to borrow £7,500 for wages, at interest not to exceed 5 per cent., and instructed him not to act as manager for more than three months without coming to the Court. He also directed the receiver to apply to the Court in the event of his wishing to enter into any further or fresh contracts of any magnitude.

Mannesmann Tube Co. (Limited) v. Lander and Larsson.

In the Queen's Bench Division, on Tuesday, the Mannesmann Tube Co. (Limited) sued the defendants to recover £5,500 damages for alleged breach of contracts. In 1896 the parties entered into several contracts, under which the defendants purchased a large quantity of tubing, but failed to take delivery, and plaintiffs alleged that, owing to the slump in the cycle trade and a combination of cycle manufacturers to purchase none but Swedish material direct from Sweden, they had sustained a loss of £5,500. Mr. Justice Mathew gave judgment for plaintiffs, and assessed the damages at £3,000.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition ready in November.*

"Practical Notes for Electrical Students."—By Messrs. A. E Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97.' A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"Electromagnetic Theory."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s. *Nearly ready.*

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"The Potentiometer and its Adjuncts": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"The Manufacture of Carbons for all Electrical Purposes."—By Francis Jehl. *In the Press.*

"Secondary Batteries, their Design and Manufacture."—By E. J. Wade. *In the Press.*

"Practical Telephony."—By Dane Sinclair and F. C. Raphael. *In the Press.*

"Primary Batteries: Their Construction and Use."—By W. R. Cooper. *In the Press.*

"'The Electrician' Wireman's Pocket-book."—*In the Press.*

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The Electric Lighting committee of the *Salford* Corporation invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walness-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, by Dec. 1.

The Electric Lighting committee of the borough of *Middlesbro'* require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers and accessories, mechanical stokers, feed pumps, injector, economiser and electric motor; (*b*) slow speed steam dynamos and accessories; (*c*) condensing plant and pipe work; (*d*) overhead travelling crane; (*e*) switchboard and instruments; (*f*) accumulators; (*g*) trenching, cables, &c.; (*h*) meters. Further particulars are set out in an advertisement in another column. Specifications, &c., may be obtained at the offices of Mr. R. Hammond, consulting engineer to the Council, 64, Victoria-street, Westminster, S.W., after Nov. 2. Tenders to the town clerk (Mr. Geo. Bainbridge), Municipal Buildings, Middlesbro', by Tuesday, Nov. 29.

The *Great Northern Railway Co.* (*Ireland*) invite tenders for (1) Lancashire boilers; (2) engines, dynamos, pumps, steam and exhaust pipes, &c., cranes, feedheaters and tools; (3) switchboards. Further particulars are set out in an advertisement elsewhere, and copies of specifications, &c., can be obtained from the secretary, Mr. T. Morrison. Specifications may be seen, but not obtained, at the office of Prof. A. B. W. Kennedy, 17, Victoria-street, Westminster, London, S.W. Tenders must be delivered at the offices of the Company, Amiens-street Terminus, Dublin, by the 19th inst.

The *Redditch* District Council invite proposals for the wiring of premises on the hire-purchase or deferred-payment system. Further particulars are set out in our advertisement columns, and tenders are to be addressed to Mr. J. A. McMullen, M.I.E.E., consulting electrical engineer, Hornchurch, Essex.

As will be seen from our advertisement pages, the *Glasgow* Corporation invite tenders for providing and erecting switchboards and instruments at the new electricity works, Port Dundas. Copies of the specification, &c., may be had from Mr. W. A. Chamen, city

Digitized by Google

electrical engineer, 75, Waterloo-street, Glasgow, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, not later than Monday, Dec. 5.

The *Glasgow* Corporation also invite tenders for the supply of about 800ft. of cast-iron pipes (21in. diameter) and certain cast-iron pipes (22in. and 29in. diameter), with special castings for the electricity works at Port Dundas. Tenders to town clerk, by 22nd inst.

The Electric committee of the *Belfast* Corporation require tenders for the supply and erection of four 400-kilowatt steam dynamos. Some particulars are given in an advertisement on another page, and specification, &c., can be obtained of the city electrical engineer (Mr. Victor A. H. McCowen). Tenders to Sir Samuel Black, town clerk, Belfast, by noon of Thursday, 17th inst.

The *British Electric Traction Co. (Limited)* require tenders for about 400 tons of about 4in. cast-iron socket and spigot pipes for electric cables, with about 400 large socket and spigot bell mouths. See advertisement.

The *Shoreditch* (London) Vestry invite tenders for three months' supply of coal to the electricity station. Tenders to clerk by Nov. 14.

The *Hornsey* District Council invite tenders for the supply and erection of electric lighting plant at the Council's central public library, Tottenham-lane, Hornsey. Tenders to Mr. F. D. Askey, by Nov. 7.

The *Hornsey* District Council also invite tenders for the supply of 1,500 cast-iron telephone pipes and 30 telephone pit covers. Tenders by Nov. 7.

The Corporation of *Barrow-in-Furness* invite tenders for the supply and erection of cast-iron lamp columns, arc and incandescent lamps, automatic switches and fittings. Tenders to Mr. C. F. Preston, Municipal Offices, Barrow-in-Furness, by noon of Nov. 14.

The *Belfast* Harbour Commissioners require tenders for the supply of nine iron latticed-built electric light masts, 70ft. high from the ground lines with suitable base. Tenders to Mr. W. A. Currie, Harbour Office, Belfast, by Nov. 14.

The *Edinburgh* Corporation invite tenders for the following plant for their electric lighting station in McDonald-road :—(1) Marine type boilers and mechanical stokers, (2) engines and dynamos. The engines must be of the Willans or Belliss type. Tenders to the offices of the town clerk (Mr. Thomas Hunter), Town Hall, Edinburgh, by Nov. 14.

The *Leatherhead* District Council invite offers from persons willing to take over their Electric Lighting Order (1898). Offers to reach Council Offices, Leatherhead, by Nov. 21.

Tenders are invited for the supply and fixing of two engines and dynamos at the *Southampton* County Lunatic Asylum, Knowle, near Fareham. Tenders to Mr. John R. Wyatt, Knowle, by Nov. 16.

Tenders are required by the *Wimbledon* District Council for the supply, delivery and erection of transformers and accessories. Tenders to Mr. W. H. Whitfield, Wimbledon, by 5 p.m. Nov. 7.

The *East Indian Railway Co.*, Nicholas-lane, London, E.C., invite proposals for the supply of 18 instruments for nine blocks (for single line); 80 instruments for 41 stations (for double line), and six spare instruments. Tenders to secretary by 1 p.m. Nov. 23.

The Paving and Highways committee of the *Manchester* Corporation require tenders for the laying of a system of underground telephone pipes, &c. Tenders by 5 p.m. Nov. 8.

The *Cheshire* Lines committee require tenders for various stores, including telegraph materials, instruments, wire, &c. Tenders to secretary, Central station, Liverpool, by Dec. 2.

Tenders are invited for lighting the Sailors' Orphans' Homes, *Kilmalcolm*, N.B., by electric light, gas, or oil. Particulars from Messrs. D. and H. Barclay, 245, St. Vincent-street, Glasgow.

The Consul-General of the *South African Republic*, Amsterdam, requires tenders for the supply of telegraph insulators and spindles. Tenders by 12th inst, to 9, Nicolaas Witsenkade, Amsterdam.

The Municipal Authorities of *Cebreros* (Avila, Spain) invite tenders until Nov. 10 for the concession for the electric lighting of the town for 15 years. Particulars from and tenders to el Secretario del Ayuntamiento.

TENDERS RECEIVED AND ACCEPTED.

The *Sheffield* Corporation have affirmed the contract for points and crossings to be supplied by Messrs. Askham Bros. and Wilson, for use on the Sheffield tramways.

The *Burnley* Corporation have accepted the tender of the Burnley Ironworks Co. for the supply of steam piping for the electricity department, at £400. The tender of Leach's, Limited, has been accepted for mechanical stokers.

The *Bedford* Town Council have accepted the tender of Mr. J. Source for the supply of ironmongery for the electric lighting works at £11. 15s. 10d. The tender of Mr. G. Mence Smith has also been accepted for the supply of chandlery at £15. 19s. 4d.

The tender of T. Medcalf, Limited, of Bradford, has been accepted by the *Edmonton* Board of Guardians for the electric lighting of the workhouse at £2,460.

The Gas and Electric Lighting committee of the *Aberdeen* Town Council have accepted the tender of the Callender Co. for the supply of cables, and that of Mr. Alex Spark for house main services.

The Electric Lighting committee of the *Hull* Corporation have accepted the tender of Thomas Parker (Limited) for a dynamo at £1,900, and of W. H. Allen, Son and Co. for a steam engine at £2,150.

APPOINTMENTS VACANT AND FILLED.

The London County Council invite applications for the position of chief officer of tramways. Salary £1,500 per annum. Applications to the clerk, County Hall, Spring-gardens, S.W., by 10 a.m., Nov. 14.

Agents are required by Messrs. W. M. Still and Co., of 24, Charles-street, Hatton Garden, London, E.C., for the sale of the "Still" incandescent electric lamp in all parts of England. See advertisement.

Agents in this country are required by M. A. Larnaude for the sale of incandescent lamps of his manufacture. See advertisement.

The Electric Light committee of the Southampton Town Council have appointed Mr. F. Hardress Chaplin (at present chief assistant engineer at Portsmouth) to the position of borough electrical engineer, in succession to Mr. J. H. Lee, at a salary of £250 per annum.

Mr. Thomas Reid, of Dundee, has been appointed to the post of head teacher of the engineering department at the Birmingham Municipal Technical School.

BUSINESS NOTICES.

Messrs. Gambrell Bros., electricians and manufacturers of scientific instruments and apparatus, have taken premises at 17, Giltspur-street, London, E.C. The new firm announce that they have had large practical experience in electrical testing and scientific instruments and that all work entrusted to them will be executed under the personal supervision of members of the firm.

Messrs. J. G. Goulding and G. F. Rimmer (trading as Goulding, Rimmer and Co.), electrical engineers, 8, Drury-buildings, 23, Water-street, Liverpool, have dissolved partnership.

Mr. Frederick William Ames has withdrawn from the partnership of Ames, Garrard and Co., art metal workers, &c., 1 and 2, Goldney-place, Harrow-road. Debts by Messrs. F. T. Ames and W. C. Garrard, who continue.

As already announced in these columns, the business of George F. Milnes and Co., Birkenhead, has been turned into a limited liability company. The new company, which has adequate capital for filling all contracts for tramway and light railway rolling stock, has taken over all the stock and assets of the old firm. Mr. G. F. Milnes and Mr. A. Hughes occupy the positions of managing director and director of the car construction department in the new company. The partnership hitherto existing between Messrs. Milnes and Hughes has been dissolved.

Messrs. Williamson and Joseph notify that Mr. A. E. Bennett is no longer in their employ.

The offices of Le Carbone, of Carteret-street, Queen Anne's-gate, S.W., will, from the 11th inst., be removed to 36, Lime-street, London, E.C.

Thomas John Palmer and Russell Oswald Wright, trading as electricians, &c., under the style of Russell O. Wright and Co., at Blackburn and Darwen, Lancs., have dissolved partnership. Debts by Mr. Palmer.

BANKRUPTCIES, LIQUIDATIONS, &c.

Mr. J. H. Fox, c/o Wm. Gray and Co., Hull, has been appointed trustee in the bankruptcy of C. H. Kitching, electrical engineer, &c., 20, St. Hilda-street, 172, Beverley-road, and 42, Chariot-street, Hull.

In the London Bankruptcy Court on Tuesday, a receiving order was made against Claude Vautin, electro-chemist, metallurgist, &c., lately carrying on business at 66, Old Broad-street, E.C., and residing at Hamilton-terrace, St. John's Wood, London. It was alleged as the act of bankruptcy that debtor has departed out of England with intent to defeat or delay his creditors. It is further reported that debtor, when leaving England, had in his possession £5,000 in Bank of England notes, a large sum in gold, and a large quantity of bearer bonds in American railways. The amount is variously given from £15,000 to £70,000.

A statement of affairs in the failure of Jacob Gütmann, trading as J. Goodman and Co., shows liabilities £3,850. 15s. 8d., deficiency ditto. The assets appear to comprise shares scheduled at £4,000, but of uncertain value. Mr. B. Newstead, 3, Church-passage, Guildhall, London, E.C., is trustee, with a committee of inspection. The bankrupt is 25 years of age, and started business

Digitized by Google

in 1893 as the Victoria Lamp Maintenance Co., and shortly afterwards, having inherited about £500, commenced trading as J. Goodman and Co., electrical engineers and fittings dealers. On April 7 last the business, which was then insolvent, was converted into a private limited company, with debtor as managing director at £5 per week, and receiving 4,000 fully paid-up £1 shares. Failure is attributed by bankrupt to want of capital and losses in trade.

At a meeting of J. Goodman and Co. (Limited), electrical engineers and fittings dealers, on Oct. 12, it was decided to wind up the company voluntarily and to appoint Mr. J. F. Lovering, 3, Church-passage, London, E.C., liquidator.

The public examination of E. A. Ingold, electrical engineer, 66, Wandsworth Bridge-road, London, S.W., was held last week at the London Bankruptcy Court. Liabilities are given at £1,790. 10s., assets £2. Debtor commenced business at Ilford in 1892 with £100 capital, and had since traded at various addresses, alone and in partnership. Failure caused by loss of £1,000 at law, £200 in attempting to float a company, and a £300 liability attaching to one of his patents. Examination concluded.

CATALOGUES, PRICE LISTS, &c.

Messrs. Newsome, Pinching and Co. forward a price list of cast-iron accessible bends, arc lamps, &c.

A list of scientific specialities patented and manufactured by Messrs. A. J. Beaumont and Co., of York, is to hand, and includes a number of automatic and hand-feed arc lamps, resistance frames, projectors, &c., for use for cinematograph displays, and for other purposes.

A list of British-made machine tools, travelling cranes, hoisting tackle, &c., for which Mr. Henry Pynegar, 5, Dowgate-hill, London, E.C., is agent, has been forwarded to us. Particulars are given of a large variety of English-made machines and accessories.

Liquidation Petition.—A petition for the winding up of the Apostoloff Automatic Telephone Parent Syndicate (Limited) has been presented to the High Court by Messrs. J. A. White and E. I. de Buriatte, 38, Holborn-viaduct, London, E.C. The petition will be heard on 9th inst.

Sale by Tender.—Mr. J. H. Thornton, liquidator of the National Company for the Distribution of Electricity by Secondary Generators (Limited), offers for sale by tender certain patents for secondary generators belonging to the said company. Tenders to Mr. Thornton, 2, Warwick-street, London, W., by noon of Nov. 28.

Enclosed Arc Lamp Patents.—We are informed that the Jandus Arc Lamp and Electric Co. have retained leading counsel and experts in connection with the case which is pending between themselves and Messrs. Beanland and Perkins over the "Ajax" lamp. After the legal proceedings have started it is said to be unlikely that the company will grant further licences.

The "Strela" Enclosed Arc Lamp.—Messrs. Krupka and Jacoby, of 61-62, Watling-street, London, E.C., forward us some particulars of the "Strela" enclosed arc lamp, for which they are agents in this country. The lamp is made for continuous or alternating currents, and is claimed to be of very simple mechanism, burning with one pair of carbons up to 200 hours. We learn that this lamp is in use by several electricity supply undertakings in this country.

New Portable Testing Battery.—Messrs. Niblett and Sutherland send particulars of a new battery which they have recently introduced, for which lightness and compactness are claimed.

"Cassier's Magazine."—The contents of the November issue of this magazine include "Electric Power in Mining," by John McGhie; "Mechanical Draught for Steam Boilers," "Pneumatic Grain Elevators and Conveyors," "Mine Timbering in the United States," "Coal Washing," "Compressed Air on Warships," "The Distilling Ship 'Iris' for the United States Fleet," and a biographical sketch of Sir William Arrol.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Oct. 26 to Nov. 1, with the ports of destination:—

Argentina—Buenos Ayres, £797 (including £474 telegraph material). *Australasia*—Adelaide, £51; Lyttelton, £17; Otago, £63; Rockhampton, £8; Sydney, £446. *Belgium*—Antwerp, £35; Ostend, £45. *Brazil*—Rio Janeiro, £186. *Burma*—Rangoon, £49. *Ceylon*—Colombo, £72. *China*—Shanghai, £14; Tientsin, £80. *Egypt*—Alexandria, £40; Port Said, £11,520 (telegraph cable). *France*—Boulogne, £216; Paris, £25. *Germany*—Hamburg, £50. *Holland*—Amsterdam, £207; *Hong Kong*, £514. *India*—Bombay, £486; Calcutta, £188. *Italy*—Spezia, £121. *Japan*—Yokohama, £600. *Malta*—£47. *Mexico*—Vera Cruz, £51. *Norway*—Christiania, £150; Christiansand, £46. *Russia*—Helsingfors, £19. *Siam*—Bangkok, £270. *South Africa*—Cape Town, £271; Durban, £135; East London, £10; Port Elizabeth, £198 (including £180 telegraph material). *Spain*—Santander, £7. *Sweden*—Gothenburg, £46; Stockholm, £613 *Turkey*—Constantinople, £14. *Uruguay*—Monte Video, £3 (telegraph material). Total £17,710, against £10,354 in the corresponding week last year (Oct. 27 to Nov. 2).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Alleged Fraud.—Ernest John Thomas, alias Ward Thomas, electrical engineer, of Drayton House, Laira, Plymouth, was again brought up at Exmouth Police Court, on Thursday, on the charge of obtaining goods from various electrical and engineering firms by false pretences, Accused was committed for trial.

Arbroath.—The Town Council have decided in favour of applying for electric lighting powers.

Aston.—The question of utilising the heat from the refuse destructor in the generation of electric current has been reported upon by Mr. J. C. Vaudrey, of Birmingham, who points out that the saving effected by using the destructor heat would be apparent only in the early stages of the supply, as on the demand becoming greater the dependence on coal will increase, and a point will be reached when the saving by the use of the destructors will be more or less lost. Mr. Vaudrey does not, however, condemn the proposal to utilise the destructor heat for a smaller plant to be used in connection with the yard lighting. The council are recommended to provide a plant for lighting the buildings, yard, and fire-station at Chester-street. The whole work of improving the present destructor, building new cells, and providing electric plant, is estimated to cost £11,500, and application is to be made for powers to borrow this sum.

Barnsley.—A Local Government Board inquiry has been held into the application of the Town Council to borrow £25,000 for electric lighting purposes. The town clerk (Mr. H. Horsfield) gave evidence in favour of the application, and the consulting electrical engineer (Mr. T. L. Miller) gave technical details of the scheme. It was proposed to lay down plant capable of supplying current to the equivalent of 6,000 h.c.p. lamps. The three-wire system of distribution would be employed, and the plant would be so designed as to supply current for tramway purposes. Provision had been made so that the available capacity of the plant could be doubled for an expenditure of £2,000 on plant and £500 on buildings. There was no opposition.

Bath.—At a meeting of the Electric Lighting committee last week, Mr. R. Hammond presented his monthly report on progress in the erection of the electricity works. The first set of generating plant had been working satisfactorily for some weeks, and the second set would be running about Christmas. The question of introducing electric tramways has been referred to the Works and Surveying committees for consideration and report.

Belfast.—At the meeting of the Electric committee last week, the city electrical engineer (Mr. V. A. H. McCowen) submitted an estimate of the cost of laying mains from the station to Mountpottinger Junction. One side of the route would cost £2,178; both sides £3,477. The matter will come before the next meeting.

Brentford.—The Highways committee, at a meeting of the Middlesex County Council, reported having considered drawings from the London United Tramways (Limited) in connection with electric tramways for Brentford, Hounslow, Hanwell and Acton. The committee approved these plans, and this approval has been endorsed by the Council.

Brentwood.—The Parish Council is not satisfied with the presen lighting arrangements, and the Lighting committee has been instructed to obtain information concerning electric lighting. The Council have decided to oppose any application for a provisional order for the district.

Buenos Ayres.—The Capital Tramways Co. has now 14¾ miles of tramways in this town which are operated electrically, the section between Comercio and the Government House, Plaza de Mayo, recently under conversion from horse to electric traction, having been inaugurated on the 27th ult. La Capital (Extensions) Company successfully inaugurated their electrical service out to the Nuevo Chicago on Sept. 11.

Chelsea (London).—The Lighting committee of the Vestry are considering an offer by the Chelsea Electricity Supply Co. to provide current for public lighting at cost price. The Vestry could provide the necessary arc lamps, standards, &c., or the company would provide the necessary capital therefor (for a 14 years' agreement), charging 6 per cent. per annum, and a renewals fund to provide for the replacement in 20 years. Repairs of lamps, standards, mains, &c., would be at the cost of the Vestry.

Chichester.—The city surveyor has been instructed to prepare a report for the City Council on electric lighting for the streets.

Church Lighting.—St. Mildred's Church, Bread-street, London, is now lighted electrically.—The electric light has recently been introduced into St. John's Church, Hastings. The vestry and school are also lighted electrically.

Digitized by Google

Colombo (Ceylon).—The Fort will shortly be lighted electrically. The contractors (Messrs. Boustead Bros.) hope to have the work completed by Jan. 1. Thirty Jandus arcs will be employed.

Diss.—The Town Council have received from Mr. Napier Prentice, Secretary of the Suffolk Electricity Supply Co., a request for permission to erect overhead electric wires in the district. A decision has not yet been come to, but no opposition is likely to arise.

Dublin.—Sir F. Marindin opened an inquiry here on Wednesday into the application of the Dublin United Tramways Co. for authority to increase the speed of the electric trams on their Dublin and Clontarf and Dublin and Dalkey sections. In opening the inquiry, Sir F. Marindin said that in the case of the Clontarf line there was no limit of speed specified in the Order, and the Board of Trade had now to decide what a safe speed meant. As to the other line, the Board were advised that as eight miles an hour was the scheduled speed, it was outside their powers to increase that maximum. Therefore the company went for an Act last year and obtained it, and under that Act the Board of Trade had now the power to increase the speed to whatever they thought safe. But they must not exceed the maximum speed allowed on the Clontarf line. It was decided to deal with the Dublin-Clontarf section of the application first. The Clontarf Commissioners had passed a resolution that the speed of the trams should not at any time exceed 10 miles an hour. The county inspector of the Royal Irish Constabulary (Mr. Alcock) said in his opinion the cars could be allowed with safety to travel at 12 miles an hour. At night the speed should not exceed 10 miles an hour. Several other witnesses concurred. Mr. Campbell, Q.C., M.P., who appeared for the Dublin, Wicklow and Wexford Railway, to oppose the application, contended that sufficient notice of the holding of the inquiry had not been given. Sir F. Marindin said he would close the inquiry as to the Clontarf line. The inquiry into the other section would be postponed in order that a fortnight's notice might be given.

Dudley-Wolverhampton Tramways.—The purchase of the Dudley, Sedgley and Wolverhampton tramways by the British Electric Traction Co. is almost completed. The Company will continue to work the existing lines by steam until the work of reconstructing and electrically equipping the Dudley-Stourbridge line is completed. It is proposed to unite the Dudley and Stourbridge line with the Dudley and Wolverhampton line by extending the latter in two directions, from Priory-street and Stone-street and from Wellington-road. The method of construction and equipment of the Dudley, Sedgley and Wolverhampton line will be the same as that adopted on the line from Dudley to Stourbridge.

Electricity in the Printing Office.—The *Rangoon Times* has now 12 English cylinder printing machines worked by electric motors, these latter made in the States.

Electric Railways in Shanghai.—This plan for these railways contemplates about 18 miles of railways on the overhead trolley system. The routes are to be three in number, viz. :—(1) From the French waterworks along the Chinese Bund (if practicable), and thence along the French and English Bunds, to the point by way of Broadway, Seward, and Yangtzepoo roads ; (2) From the Bund to the Bubbling Well, by way of the Kiukiang, Kiangse, Hankau, and Nankin roads ; (3) From the Shanghai station of the Woosung-Shanghai railway to the west gate of the Chinese city. A concession is to be given for the construction of the line and all accessories to the Shanghai Tramway Company. The concession is to be for 30, 40, or 50 years, according to the tender the ratepayers may decide to accept, and the company is to pay the council a percentage of the total gross receipts for the period of the concession. Notification to tenderers by public advertisement will follow in due course, and the tender finally selected will be submitted to the ratepayers for ratification.

Electric Trains in Belgium.—An experimental trial of an electrically-drawn train has just been made on the Brussels-Liège railway system. A special train made the journey between Renory-Liège and Tirlemont, and back, stopping on the way at the principal stations. The experiment was, it is reported, a complete success, and the substitution of electricity for steam, at any rate on one of the fast day trains to begin with, is mentioned.

Employers' Liability.—At Brompton (London) County Court a labourer named Pearson succeeded in obtaining compensation for an accident which took place in May last at the works of the Charing Cross and Strand Corporation, Commercial-road, Lambeth. Pearson was wheeling a barrow of cement along some planks, which owing to the wet had warped, when the wheel of the barrow fell between and Pearson was overturned. His wages were £1. 9s. 2d. per week, and he claimed £150, obtaining a judgment for £60 and costs.

Erith.—A special meeting of the District Council was held last week to sanction an application to the Board of Trade for a provisional order. A formal resolution authorising that application was unanimously agreed to.

Exhibition.—There is to be a provincial exhibition at Ghent in the summer of 1899, at which a section will be devoted to lighting, heating and ventilating apparatus. All particulars can be obtained from the executive committee, 47, Boulevard Léopold, Ghent, Belgium.

Fiji.—Among the public works in course of construction in Fiji is a telephone line 100 miles in length, from Suva to Ba, through Kausori, Viria, Vunidalva and Nadarivatu. The line is to be worked by the Government, the Colonial Sugar Refining Co. and the Union Steamship Co.

Glossop.—The Town Council have decided to apply for a provisional order. The question of transferring the order to a company will be considered at a special meeting of the Council on Wednesday next.

Grays (Essex).—Mr. A. H. Preece has been appointed consulting engineer to the District Council at a fee of 50 guineas.

Great Yarmouth.—A special meeting of the Town Council was held on Monday to consider a scheme for the construction of electric tramways in the town, at an estimated cost of £40,000. The total length of the projected lines is 3¾ miles. Current will be supplied from the Corporation's mains, and the lines will be equipped on the overhead system. The Council are in favour of the project.

Hull.—A Local Government Board inquiry was held here on Tuesday into the application of the Town Council to borrow, amongst other sums, £26,000 for electric lighting purposes and £4,103 for a refuse destructor. Evidence in support of the application was given by the Town Clerk, the City Engineer, and Councillor Skinner, and technical details were submitted by Mr. A. S. Barnard, the borough electrical engineer.

Mr. Barnard has prepared a report, in which he states that the demand for current renders it necessary to again consider the question of making additions to the generating plant. Before the winter of next year, the plant will be insufficient to meet the demand, and it is necessary to place the orders for the engine and dynamo now and the remaining plant later. He recommends that application be made for sanction to a loan of £16,000 for these extensions, and the Electric Light Committee have endorsed his recommendation.

Ilfracombe.—The Town Council have invited the local gas company to make an offer for the transfer of the Ilfracombe provisional order. A London company has already submitted terms for leasing the order, but members seem disposed to give preference to the local company.

Kirkcaldy.—A unanimous resolution in favour of applying for a provisional order was passed by the Town Council on Saturday.

Lambeth.—The Vestry have decided to defer for a week the question of appointing a committee of eight members to investigate the statements and charges made in connection with the transfer of the Vestry's provisional order. At the next meeting Mr. Price will move that those members who voted against the Vestry exercising its electric lighting powers be asked to sign an undertaking to take no legal or other action if Messrs. Hubbard, Wightman and Lock will attend the committee and state particulars of the information which they declare to be within their knowledge.

Law Courts (London).—The electric light has now been laid on at the quadrangle entrance and for the whole of the basement of the main block of the Royal Courts of Justice. In a short time the whole of the Courts will be lighted electrically.

Light Railways.—It is proposed to construct an electric tramway for Esher, Ditton, Surbiton and Kingston-on-Thames. The promoting syndicate offer to take current from the Kingston Corporation, and the lines, if the sanction of the interested local authorities can be obtained, will be equipped on the overhead trolley system.

The Light Railway Commissioners recently held an inquiry into the application to construct a light (electric) railway from Redditch to Astwood Bank. The Redditch District Council opposed the scheme, on the ground of the narrowness of one of the main streets, and the Commissioners intimated that the objection was a vital one. Efforts are being made to induce the Council to reconsider their attitude. As a result of negotiations, the Council, who favour generally the principle of the scheme, have decided to approach the owners of property in the narrow thoroughfare.

The Atherton District Council have unanimously resolved to support the scheme for the construction of a light electric railway from the terminus of the St. Helen's tramway system to Bolton.

Lincoln.—The City Council decided on Wednesday to apply to the Local Government Board for sanction to borrow a further £19,000 for electric light extensions. Alderman Page said they applied to the Local Government Board to borrow, and it was stated that they proposed to spend £22,000. It was satisfactory to know that that expenditure for what they proposed to do was not likely to be exceeded, and that there was every probability that towards the end of the month the Corporation would be in a position to commence electricity supply. A considerable extension of plant would be necessary if the requirements of the year 1899 were to be reasonably met, and additional capital would be required. £19,000 would enable them to increase the mileage of cables from four to

Digitized by Google

something like 10 miles, and would also enable them to increase the capacity of the station from the equivalent of 5,000 to 18,800 8 c.p. lamps.

Llandudno.—The Electric Light committee of the District Council have decided to switch on electric current for the first time to-morrow (Saturday) evening. The formal opening of the works has been postponed until the spring of 1899.

London County Council.—At Tuesday's meeting the Finance committee reported on an application from the Newington Vestry for a loan of £50,000, repayable on the instalment system within 42 years, to defray the cost of the installation of the electric light in the parish. The Vestry asked that £10,000 be advanced at once, and they proposed to take up the remaining £40,000 in instalments of £10,000 as required, and to postpone the repayments for five years in each case, from the date of the advance. This was the first case in which the Council had been asked to sanction the postponement of repayment, and the committee thought that such a postponement might in certain cases be allowed, but were not prepared to recommend that the repayment of the instalments should in this instance be deferred for so long a period as five years. The Vestry had agreed that the repayment of principal should be postponed until after the expiration of three years from the date of the advance of the loan, and the committee recommended that the loan be made on those terms. Approved. A further loan of £10,470 (balance of a loan of £22,949 to defray the cost of the purchase of land and the installation of electric light in the parish) was made to the Shoreditch Vestry.

Malta.—£9,123 was collected as revenue from the municipal electric lighting undertaking in 1897, against £347 in 1896 (the station was open for one month). Nearly £7,000 of this sum was paid by the Government for street lighting, and a further portion for the lighting of military and public buildings. The cost of street lighting in Malta by the adoption of electricity has somewhat increased, but general satisfaction is expressed at the vastly superior lighting which is now a conspicuous feature of the main thoroughfares.

Newington (London).—At the meeting of the Vestry, last week, the Electric Lighting committee brought up a report recommending the appointment of Mr. J. H. Lee, late borough electrical engineer at Southampton, as electrical engineer to the Vestry at a salary of £250 per annum. Considerable discussion ensued, and eventually it was decided to advertise the position, and that a salary of £250 a year be offered.

Newmarket.—The Newmarket Electric Light Co. hope to be able to commence supply in December.

Orrel (Liverpool).—An interesting experiment is being made in this district by Mr. Jones, proprietor of large brickworks, in the lighting of the houses of the workmen employed at the works. For the accommodation of his workpeople and others, eight streets have been formed, with 76 houses in each, or about 600 in all. It is Mr. Jones's intention to supply electric current to each of the houses, which are rented at 5s., 7s. and 8s. per week. The estimated initial cost of the electric lighting installation to supply between 2,000 and 3,000 lights is estimated at £3,000. To the 5s. house two 8 c.p. lights will be allotted, to the 7s. house three lights, and to the 8s. house four. These will be supplied at a charge, including the fittings, of 3d., 6d. and 9d. per week respectively.

Police Telephonic Communication.—Attention is called to the remarkable fact that neither the City nor the Metropolitan police services are in telephonic connection with the system of the National Telephone Co., so that in the event of a police officer being hastily required it is necessary to either telegraph or employ a messenger. Seeing that the telephone is available in thousands of places where prompt assistance could be obtained if this telephonic communication were established, it seems most remarkable that this connection has not been made before now. It is also asserted that the Metropolitan Fire Brigade arrangements, so far as the telephone is concerned, are of a somewhat primitive character.

Portobello.—A lengthy report on the subject of the motive power to be used on the Portobello tramways is just published. The report is by Prof. A. B. W. Kennedy, and was presented to the Edinburgh Corporation as far back as February last.

Provisional Order Notices.—The District Councils of Knutaford and Rugby, and the Vestry of St. Mary Abbotts, Kensington, London, give notice of intention to apply for provisional orders.

Rathmines and Rathgar (Dublin).—A Local Government Board inquiry will be held here on Monday into the application of the Township Commissioners to borrow £50,000 for electric lighting purposes.

Retford.—The Town Council decided on Monday to apply for a provisional order. An arrangement has been made with a company for carrying out the provisions of the order as soon as it is obtained

Sebastopol (Russia).—This town is provided with an excellent electric lighting installation and also with electric tramways. The necessary capital for these ventures was subscribed by French and Belgian capitalists. This is, a correspondent writes us, another case where the British contractor has been forestalled.

Sheffield.—The Tramways committee of the Corporation have decided that, as soon as the whole of the electric cars are running, advertisements on these cars shall be entirely discontinued.

Shoreditch (London).—The Lighting committee have considered a report from Mr. Newton Russell, the chief electrical engineer, concerning applications for the supply of electric current from the Haggerston district. From a personal canvass, it has been found that more than a sufficient number of persons had promised to take a supply to justify putting down a sub-station in that locality, which the committee recommended should be done, at a cost of £2,200. The recommendation was adopted. The committee further recommended the purchase of a further supply of meters, at a cost of £520. Approved. The Lighting committee have been empowered to advertise for tenders for the sinking of a well at the Coronet-street works.

Siam.—General complaint is made of the deplorable condition of the telegraph lines in Siam and the consequent lack of telegraphing facilities. In the southern districts the lines are down in all directions. The short subaqueous cable connecting the mainland with the island of Koh-si-chang, in the Gulf of Siam, where large steamers load, was laid last year, and has been found of great service to commerce; but regarding the land lines complaints are general. The telegraph and postal department of Siam are separate, to which fact the unsatisfactory condition of things is attributed. It is suggested that the appointment of a competent European officer to take entire charge of the land lines would have the effect of speedily improving matters.

Sleaford.—A meeting of the Tradesmen's Association was held last week to consider the question of improving the lighting arrangements. An electrical engineer was present and answered questions as to the cost, &c., of electric lighting, and eventually it was resolved to ask the District Council to appoint a sub-committee to go fully into the matter, in order that a definite scheme might be brought forward. Should the Council decline the overtures of the Association an attempt will be made to form a local company to establish electricity works.

South Africa.—A company, entitled the Umtali (Rhodesia) Electric Power Company (Limited), has been formed with a capital of £25,000 for putting down an electric water-power mining plant at the Penhalonga gold mines, Rhodesia. The plant is to consist of five 100 H.P. and two 50 H.P. dynamos, and five motors of 50 B.H.P. each, besides two 250 H.P. Pelton water wheels.

The Cape Town Council are about to place an order with the Jandus Co. for the supply of 30 enclosed arc lamps.

Southampton.—The Town Council have rescinded their recent resolution in favour of adopting the overhead trolley system of traction on the tramways, and the Tramways committee have been given 12 months' further time in which to investigate the most suitable form of traction for the lines.

Steam Omnibuses.—Mr. E. H. Bayley presided on Monday at a meeting of the London Steam Omnibus Co., and expressed his full confidence in the future of the concern. The company work the French De Dion steam-car engine, as well as the German Daimler petroleum machine. It was stated by the Chairman that the steam 'buses can be worked at a cost of about £9. 10s. per 'bus per week, against £15. 10s. for a horse-driven vehicle. It was announced that 14,800 shares of £10 each had been allotted, and that two steam and two petroleum 'buses had been built for the company.

Sydney (N.S.W.)—The telephone is increasing in favour in this city. A large number of applicants have applied, both in the city and suburbs. In August 113 connections were made—30 central, 70 branch, and 13 country exchange lines. The totals for June and July were 134 and 140 respectively. Since Jan. 1 the number has been 1,367, the total number at the end of Sept. was 7,745. The number of telephones in use at the end of August was 8,677. The receipts from the Newcastle line for August were £75. 12s. 6d., bringing the total revenue from the line for the eight months during which it had been established up to £464. 7s. 6d. During the months of June and July the receipts from the same source were £76. 18s. 9d. and £67. 13s. These figures are considered highly satisfactory. The telephone service is under Government control.

The Telegraph in the Congo Free State.—The expedition of Mr. D. Mohun, which will, as previously announced in *The Electrician*, construct the telegraph line from Lake Tanganyika to Stanley Falls, has now completed its number, and has left Zanzibar for the interior. The expedition is elaborately organised and equipped, and numbers, it is said, 12,000 persons.

Twickenham.—A discussion arose at the meeting of the District Council, last week, upon the advisability of allowing a company to obtain a provisional order for the district. The usual arguments

Digitized by Google

for delay were used, and Mr. Webb asserted that "electric lighting was now in its infancy"—a remark which shows he is up to date. No decision was arrived at by the Council.

Water Power Utilisation in Canada.—The *Commercial Advertiser*, of New York, states that work has been begun in connection with the ambitious plan of the Shewanagan Water and Power Co. for the development of the power of the St. Maurice River at the Shewanagan Falls, near Three Rivers. A contract has been let to Messrs. Barry, Ross and McRae for the construction of electricity generating plant, which will cost over $1,000,000, and take over a year to complete. Besides supplying current for light and power, it is proposed to run an electric line to Three Rivers, 19 miles away, and the transmission of power to Montreal, 80 miles away, is also mooted.

Winsford (Cheshire).—The District Council is at present considering the advisability of adopting electric lighting, and it is probable that a provisional order will be applied for.

Wolverhampton.—At a special meeting of the Council last week Ald. Mander, chairman of the Lighting committee, said that the breakdown of the electric light on the previous Saturday was due to the fact that the Art Gallery transformer station was unsuitable for its purpose. It was so damp that water had to be pumped out of the transformer beds daily. He understood that this was due to the rain-water sewers being above the level of the station, but certain alterations had now been made. With regard to the possibility of the tramways being worked by electricity in the future, he thought that in addition to the £33,000 which was being asked for to extend the generating plant, another £5,000 or £10,000 should be granted to bring it further up to date.

Workhouse Lighting.—The Barton (Lancs.) Guardians have instructed Mr. G. R. Peers to prepare a report on electric lighting of the workhouse, and particularly as to the advisability of taking current from the Eccles Corporation mains.

Staff Dinner.—The annual staff dinner of the Electrical Power Storage Co. took place at the Holborn Restaurant, London, on Monday last, when 36 members of the staff sat down. Mr. J. Irving Courtenay, chairman of the company, presided, and was supported by Mr. Frank King. Music, singing and thought-reading interpersed the usual toasts.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

October 14, 1898.

21,633. G. HOOKHAM. London. Improvements in electricity meters.
21,652. S. WORTHINGTON and R. J. CROWLEY. London. An improved system of electric traction.
21,669. J. W. SWAN. London. Improvements in or connected with incandescent electric lamps.
21,689. W. LANGDON-DAVIES, London. Improvements in induction motors.

October 15, 1898.

21,695. E. A. STOKES, E. J. STOKES and R. J. CROWLEY. London. A circulating electric battery.
21,715. J. FERGUSON and J. WHITE. Glasgow. Improvements in automatic means of breaking electric circuits.
21,716. W. THOMSON, Baron Kelvin of Largs. Glasgow. Improvements in electric measuring instruments.
21,718. ENGLISH INDUSTRIALS (LIMITED). London. Improvements in electric arc lamps. (Elektricittäs Aktiengesellschaft, Germany.)

22,545. W. P. THOMPSON. Liverpool. Improvements in automatic telephone exchanges. (The Strowger Automatic Telephone Exchange, United States.)*

22,547. S. HARRISON. Liverpool. Improvements in appliances or apparatus for automatically replacing fuses in electric light and power installations.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1897.

22,444. W. P. DRABBLE and F. E. BRACEWELL (executors of the late J. W. Hulse). Machinery or apparatus for transmitting motion from electric motors to other machinery.

22,717. PHILLIPS. Interrupters for electrical circuits, more particularly applicable to induction coils.

22,978. PESCHEK. Fusible cut-out for electric lighting and the like.

23,097. NISBETT. Electrical conductor or cable.

24,051. FABIAN. Electrodes for primary and secondary batteries in chemical cells.

24,884. HARRIS. Electro-deposition apparatus.

25,061. TURNER, TURNER, TURNER and AVEYARD. Switches for electric motors.

25,183. DARRAH and GIBSON. Brackets, chandeliers, electroliers and the like.

25,245. LAKE (Cantono). Method for varying the speed of electric motors or the electromotive force of dynamo-electric machines.

25,412. GAMBRELL and HARRIS. Electrical resistances.

25,434. DAWSON. Trolley wire hangers for use in overhead lines of electrical railways or tramways.

25,582. H. M. L. CRONAN. Electric lighter for gas and petroleum motors.

25,599. CHAMBERLAIN AND HOOKHAM (LIMITED) and HOLDEN. Electricity meters.

25,647. DUNLAP. Manufacture of globes and shades for electricity and other lamps.

26,057. BAIR. Porous cells or receptacles for galvanic batteries.

1898.

12,763. THOMPSON (Maggiorani). Apparatus for electro-therapeutic purposes.

13,273. THE BRITISH THOMSON-HOUSTON CO., LIMITED (Steinmetz). Systems of electrical distribution.

15,300. SNOW. Electrically heated rolls for drying paper or fabric and for similar purposes.

15,430. THOMPSON (Langguth). Diaphragm for electrolytic apparatus.

16,834. PETERSEN. Means for the automatically regulated charging of electrical accumulators.

COMPANIES' MEETINGS AND REPORTS.

Monte Video Telephone Co. (Limited).

The annual general meeting of this Company was held on Monday at Winchester House, Old Broad-street, London, under the presidency of Mr. HERBERT WARD.

The SECRETARY (Mr. E. M. Reiss) having read the notice calling the meeting,

The CHAIRMAN said: In comparing the past year's working with the previous year I have again the pleasure of reporting an improvement in the Company's business, which, if small, is certainly appreciable, and marks continued progress. The subscriptions show an increase of £640, the number of subscribers being 108 more on July 31st than at the corresponding date last year, and the subsequent two months show a further increase of 32. The working expenses at Monte Video were £400 heavier. This increase, however, was not all due to extra expenditure consequent on the increased number of subscribers, but also to an unusual number of changes in the list of subscribers, which entailed continued expenditure for removals and repairs to instruments, and helped to swell our working expenses. The last debit item in the profit and loss account is £388 written off the stock of materials in Monte Video. It will be recollected that £800 was written off last year, when I explained that much of the stock comprised old materal that was now almost obsolete; and in order to bring the amount carried in our balance-sheet still nearer its realisable value the Board decided to write off this further amount this year. Referring to the balance-sheet, the only item on the side of liabilities I would refer to is that of sundry creditors, £1,951, in order to tell you that this item chiefly consists of the balance of a loan against securities from our bankers for dividend purposes, which is to-day all repaid. Under the head of assets we show the £60,000 by which our capital has been reduced deducted from the original purchase price of the property. The additional capital outlay for the year of £1,675 is small in proportion to the increase of 108 subscribers, and represents the additional money put into the business in the shape of new instruments, new wires and poles, &c., the item being partly provided for out of revenue by the £1,000 placed to reserve. Freehold premises stand at £500 more than before, owing to the purchase for that amount of one of our sub-office buildings, the Paso del Molino. I may mention that as an investment this item of freehold property in Monte Video represents in annual rent saved, and rent now obtained from sub-letting a small portion, a return of 7 per cent. per annum. Stock of materials in Monte Video, £1,728, is the reduced value after the amount written off this year. Sundry debtors (£2,108) are chiefly subscribers for outstanding subscriptions, all of which amount is considered good and collectable, as far as can be judged at present. The item of securities stands in the balance sheet at cost price; they are to-day worth £900 more. With reference to the rearrangement of the capital of the Company, as was announced in the report, the Court confirmed the reduction of the Ordinary share capital by £60,000 on October 19th. The time at our disposal since has been quite insufficient to arrange with the holders of the Company's promissory notes for their exchange for Preference and Ordinary shares. These shares have yet to be allotted, and before this can be done it is necessary, in order to protect them as fully paid, to file a contract or contracts at Somerset House between the Company and the noteholders. The preparation and execution of this contract may take considerable time to accomplish. The Board had anticipated that it might be possible at this meeting to recommend a dividend on the Ordinary as well as on the Preferred shares. It was not possible to say in the report that they would do so, for the advisability of such a recommendation depended in a measure upon the receipt of the promissory notes, or of nearly all of them, before making it, and at the date of the report, of course, none had been received. Sufficient of the notes to warrant such a recommendation have not been sent in; consequently, a dividend upon the Ordinary shares cannot be recommended. There will not, in the minds of some of the leading shareholders, be any disappointment in this, as they have expressed their conviction that it is to the best interest of the Company that at the beginning of the new arrangement in regard to shares, any surplus that there may be in its funds above the payment of the full dividend upon its Preferred shares should be held as a reserve for contingencies or for dividend purposes in the future. There are, of course, two ways of looking at this matter, but undoubtedly the one stated is the safest for the Company's future, and, under the circumstances, it is the only course that can be recommended. The considerable amount carried forward adds materially to the assurance of future dividends and at the same time provides for additional capital expenditure, which is to be expected in the natural growth of the business, and these facts, the Board feel, will largely offset any disappointment on the part of shareholders who expected a small dividend on their Ordinary shares. Before closing my remarks, I must refer with regret to the enforced retirement last December, through ill-health, of our former colleague, Mr. Edward F. Powers. His seat on the Board has been filled by Mr. J. E. Kingsbury, an electrician of great experience, well known in the telephone world, whose technical knowledge is an especially valuable feature of his connection with the Company. I now move—

"*That the report and accounts for the year ending July 31st last, as submitted, be approved and adopted.*"

Mr. FRANK W. JONES, in seconding the motion, referred to the success which had attended the efforts for re-arranging the capital. At their meeting last July he remarked that under the then existing circumstances and those likely for an indefinite number of years to prevail, they could not prudently pay away in dividends a greater sum than they had been paying for several years before; and he wished now to emphasise this statement. The necessity for an ample and an available reserve in their business was very apparent to anyone who had had intimate connection with a South American Telephone Co.

A discussion followed, in the course of which Mr. LOCK referred with satisfaction to the increase in the revenue and net profits, as indicating increasing business, but confessed great disappointment at the way in which it was proposed to deal with the net profit. He suggested that the Directors would be acting wisely if they did not withhold a moderate dividend on the Ordinary shares. The amount of promissory notes required could probably be got in within 24 hours. He moved an amendment adjourning the meeting to November 14th, to enable the Directors to get in the outstanding promissory notes, after which the Board could recommend a dividend of 2½ per cent. on the Ordinary shares.

The CHAIRMAN and Mr. JONES replied, defending the recommendations in the report.

Mr. COLE supported the action of the Directors.

The amendment was not seconded, and the report was put and declared adopted.

Mr. Lock demanded a poll, which the Chairman said would be taken immediately. Mr. Lock stated that this would render the poll nugatory,

Digitized by Google

as his desire was that the shareholders might all vote. He thereupon withdrew his demand.

The dividend of 5 per cent. on the Preferred shares was afterwards declared.

NEW COMPANIES, STATUTORY RETURNS, &c.

NORTHALLERTON ELECTRIC LIGHT AND POWER CO. (LIMITED).—This company was registered on Oct. 27 with a capital of £2,000, in £1 shares, to carry on at Northallerton, Yorks, and elsewhere, the business of electricians, electrical and mechanical engineers and contractors, suppliers of electricity for the purposes of light, heat and motive power, and manufacturers and dealers in electrical apparatus of all kinds. The first subscribers are: John E. Hutton, electrical engineer (150 shares), W. J. Plews and A. de L. Long, engineer (with 10 shares each), Major W. A. Chauncey, C. E. L. Ringrose, W. G. Jackson, W. Baigent, M.D., J. A. Hutchinson, M.D., and Sir H. B. Peirse, Bart. (with five shares each).

PAYNE AND BATES (LIMITED).—This company was registered on Oct. 28, with a capital of £7,000, to acquire the business carried on by Walter S. Payne and Henry Bates under the style of Payne and Bates, and to carry on the business of general engineers, manufacturers of and dealers in electric, steam, gas, oil and other engines and motors, and parts and accessories of the same.

POROUS ACCUMULATOR CO. (LIMITED).—The statutory return to September 27 gives the nominal capital as £3,000, in £1 shares, the whole of which has been taken up, and 1,993 shares have been issued as fully paid.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 28½d. per oz. (Nov. 3). Consols (2¾ per cent.) 109—109⅛ for money, 109¼—109⅜ for account; 2½ per cent. 104—104½ (Nov. 3). Stock Exchange Settling Days: Consols, Nov. 4; Stocks and Shares Continuation Days, Nov. 9 and 28; Ticket Days, Nov. 10 and 29; Pay Days, Nov. 11 and 30; Mining Share Carry-over Days, Nov. 8 and 26.

ALDERLEY AND WILMSLOW ELECTRIC SUPPLY CO. (LIMITED).—The statutory meeting of this company was held on Thursday, last week, Mr. W. P. J. Fawcus presiding. The secretary (Mr. W. E. Rowcliffe) explained the progress made in the erection of the generating station at Belmont. It was further stated that the contract for the cables had been placed, and that the work would be proceeded with forthwith, and consumers might anticipate a supply of current in the early spring. Mr. Philip Whyman, Alderley Edge, and Mr. John Royle, Wilmslow, were elected directors.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT.—A dividend at the rate of 15 per cent. for the past year (the same as in 1897) has been declared.

COMPAGNIE DE L'INDUSTRIE ELECTRIQUE (GENEVA).—This company, which was founded originally with a capital of 2,500,000fr., made a profit during the year 1897-98 of only 1,038fr., against 18,060fr. in the previous year. This result is due to the Genoa branch establishment losing 112,028fr. against a profit of 17,631fr. in 1896-97. It has been decided to wind up the Genoa branch.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—It is stated that share certificates in this company are ready to be exchanged for bankers' receipts and allotment letters.

LINOTPYE CO. (LIMITED).—Lord Kelvin has accepted a seat on the Board of this company in succession to the late Dr. John Hopkinson.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Thursday, Nov. 10, a special settling day for 40,000 "A" £5 (£2 paid) Six per Cent. Cumulative Preference Shares (Nos. 1 to 40,000) and 27,500 "B" £5 fully paid Six per Cent. Cumulative Preference Shares (Nos. 1 to 27,500) of the Buenos Ayres and Belgrano Electric Tramways Co. (Limited), and have ordered the same, as well as the £4,000,000 Ordinary stock of the Eastern Telegraph Co. (Limited) (in lieu of the 40,000 Ordinary shares of £10 each now quoted) to be quoted in the Official List.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES CO. (LIMITED).—The eighth report of the directors of this company for the year to June 30th last, states that the accounts show a profit of £9,942. 0s. 8d., to which is added £744. 3s. 4d., brought forward. After providing for interest on debentures and dividend on preference shares, there remains £5,499. 2s. 7d., and the directors recommend a dividend at the rate of 4 per cent. per annum on the Ordinary shares absorbing £2,800; that £1,500 be written off; that £500 be carried to reserve, and that £699. 2s. 7d. be carried forward. Capital outlay for the year was £1,754. 8s. 1d., against £8,423. 8s. 7d. for the previous year. The company's property has been fully maintained. On June 30th, the number of subscribers was 2,640. During the year commerce in Venezuela has experienced considerable difficulties. An outbreak of small-pox has, in some districts, been so serious as almost to stop business.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—The Directors of this Company, after placing £8,000 to reserve, recommend a dividend at the rate of 5s. per Ordinary share (or £3. 6s. 8d. per cent. per annum) free of tax, for the six months to June 30th last, carrying forward £1,427. 18s. 11d. This company's traffic receipts for the week ended Oct. 28 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £3,255.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED.)—The estimated amount of the traffic receipts of this Company for the half-month ended Oct. 31st is £3,175, against £2,028 in the corresponding period of 1897.

NOTES.

THE annual report of the Queensland Post and Telegraph Department for the year 1897-8, which has just reached us, is not less formal and not more exciting than such Colonial publications usually are; but there is one item relating to telegraph and telephone business well worth noticing here just now. Queensland has commenced the construction of trunk lines connecting its principal urban telephone exchanges; and upon one of these lines we have the result of a full year's working from July, 1897, to June, 1898. The experiment was between Charters Towers and Townsville, and its effect was to reduce the revenue from telegrams from £76 to £52, the earnings of the trunk telephone wire rather more than compensating for this loss. Simultaneously there was a very large increase in the number of subscribers to the exchanges at both ends. Fortunately the exchanges, as well as the telegraph and telephone lines, all belong to the Government, which consequently clears a satisfactory profit on the businesses as a whole. It is a pity we cannot be supplied with similar figures for this country.

IN the POSTMASTER-GENERAL'S written reply to last week's deputation from the Manchester Corporation we have a further insight into what is to be the policy of the Department with regard to the telephones. There is, we are told, no immediate intention of establishing Post Office competition in a city like Manchester, where the Post Office has not hitherto instituted any *local* exchange. The italics in the last sentence are ours. Manchester has an exchange for the operation of the trunk wires, so has London, and so have other large towns, but these are not local exchanges. Consequently, we must assume that Post Office competition is to be confined to those districts in which it has already been tried. In fact, it would appear that the POSTMASTER-GENERAL agrees with the evidence given by the Post Office experts before the Select Committee as to the futility of telephonic competition, and his Department, having tried the experiment already, prefers to leave further trials in this direction to the municipalities themselves—if they can get powers from Parliament. These local authorities will then only have themselves to blame when their ratepayers realise the annoyance caused by having two telephone systems in the same town.

THE Corporation of London and the London County Council are also eager to know what is to be the outcome of the Select Committee's report. The former body is content to "take steps to urge upon Her Majesty's Government the extreme desirability of action being forthwith taken . . ;" but the County Council is, as usual, more energetic. They have written to the POSTMASTER-GENERAL to inquire whether there is to be competition in London, but the reply they have received is much less definite than that sent to Manchester—Her Majesty's Government are considering the report of the Committee. But the County Council will be put off with no evasive answer, and are writing again to remind the POSTMASTER-GENERAL that what they primarily want is an answer to the question, "Will the Post Office compete in London?" The County Council might read its answer in the portion of the reply to the Manchester Corporation quoted above.

THE presidential address of Mr. J. A. BRODIE before the Liverpool Engineering Society, an abstract of which will be found in another note, makes timely reference to the electric traction scheme for that city, now that the so-called experimental electric tramway is practically completed and will shortly be put in operation. Mr. BRODIE takes a sensible, business-like view of the overhead trolley system, regarding it as superior to other systems "from all points of view except that of appearance"; and he looks forward to the completion of a continuous line of surface tramways extending from Liverpool landing stage to the colliery district of Haydock, 15½ miles away. The reason there is such a pronounced foreign element in electric traction, Mr. BRODIE considers, is because we have lagged 10 years behind American and Continental engineers.

Digitized by Google

It will interest our readers to learn that in not a few places in this country time-expired men from the British navy are permanently engaged at electric supply works as foremen in charge of work on mains and in other jobs requiring some technical knowledge of electrical matters. At a time when patriotic feeling is deeply stirred it may be appropriate to refer to this fact. We may add that, quite apart from any such feeling, the employment of these men is distinctly to be encouraged, for the regular course of training they receive in electrical subjects is not surpassed by that to be had at technical colleges on land, while the discipline of their naval career has a decidedly healthy effect on their character.

Cable Interruptions and Repairs.—

	Date of Interruption	Date of Repair.
Bissao—Bolama	Aug. 3, 1898 ...	—
St. Louis and Noronha	Oct. 17, 1898 ...	—
Gibraltar—Tangier	Oct. 18, 1898 ...	Nov. 4, 1898
Pernambuco - Ceara	Oct. 19, 1898 ...	—

The Llandudno Electric Supply Station.—The electric light was switched on at Llandudno on Saturday last. An account of the combined dust destructor and electric supply station will be found in our issue of Oct. 28. The official opening has been postponed until next Easter. There are at present about 2,000 8-c.p. incandescent lamps converted to the mains and 48 arc lamps for street lighting.

Obituary.—According to the Paris correspondent of the *Standard* it appears that we have lost, under painful circumstances, another of the pioneers of electrical industry. M. de Meritens, the constructor of the historical dynamos bearing his name, several of which machines are still in use in many lighthouses, has died at Pontoise, at the age of 65. It is sad to hear that M. de Meritens was in such poverty that both himself and his wife put an end to their lives by poison.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the 7th inst., Sir James Crichton-Browne, M.D., F.R.S., Treasurer and Vice-President, presiding. The special thanks of the members were returned to Mr. John B. Carrington, for his donation of £25, and to Mr. Charles Scott Dickson, Q.C., Solicitor-General for Scotland, for his donation of £100 to the fund for the promotion of experimental research at low temperatures.

Electro-Zinc Precipitation of Gold.—In the September 17th issue of the *Johannesburg Star*, a copy of which is in our hands, there is a lengthy article descriptive of the Bettel process of precipitating gold. The process is one involving the replacement of zinc by gold, by electro-chemical action. It appears to give satisfactory results on the comparatively small scale on which it has been tried, and efforts are being made to introduce the process more widely on the goldfields of South Africa. It is claimed, among other things, that "from 2s. to 3s. more per ounce fine gold will be realised from the gold (bullion)."

Personal.—We are pleased to learn that Sir Eyre M. Shaw, chairman of the Metropolitan Electric Supply Co., who last week underwent a painful operation, is progressing satisfactorily towards convalescence.

Mr. A. H. Walton, who has been the Metropolitan Electric Supply Company's engineer for the last four years, has been appointed by the British Thomson-Houston Company chief engineer for the erection and maintenance of the electrical plant in connection with the Central London Railway, and will act as chief resident engineer when the line is in operation. We hear that Mr. R. R. Todd has been appointed Mr. Walton's successor.

The Corporation of London and the Telephones.—At a meeting of the Court of Common Council on Thursday last week, the telephone question came up for discussion. On the motion of Mr. Moojen it was referred to the Streets Committee to consider the necessity of the Corporation's applying for a licence to establish a telephone service either solely or in conjunction with the London Council. The Streets Committee submitted a report narrating the recommendations of the Select Committee of the House of Commons on the telephone service and appending a report of the City Solicitor upon it. They advised that the necessary steps should be taken to urge upon Her Majesty's Government the extreme desirability of action being forthwith taken to give due effect to the recommendations of the Select Committee. This was adopted.

The Society of Arts.—The first meeting of the new session will be held on Wednesday next, when Sir John Wolfe Barry will deliver his presidential address. Among the Papers down for reading before Christmas is one by Prof. G. Forbes on "Long-Distance Transmission of Electric Power," to be read on November 23rd. After Christmas, Papers will be read on—"Canals and Inland Navigation in the United Kingdom," by L. F. Vernon-Harcourt; "Preservation of Timber," by S. B. Boulton; "Electric Traction and its Application to Railway Works," by Philip Dawson; "Coal Supplies," by T. Forster Brown; "Wireless Telegraphy," by W. H. Preece; and "Leadless Glasses," by Wilton P. Rix. A course of four Monday evening Cantor lectures on acetylene will be commenced by Prof. Vivian B. Lewes on November 21st.

"Etherion."—In an article in the *Chemical News* of Nov. 4th, under the heading "On the Supposed New Gas, Etherion," Sir William Crookes gives an account of some old experiments of his, which would tend to show that etherion is nothing more than—aqueous vapour. After giving in detail the reasons that have made him of that opinion, Sir William concludes by admitting that he has up to the present only seen an abstract of Mr. Brush's Paper. On the evidence at present available, however, he considers it more probable that etherion is water-vapour than that it is a new elementary gas, and he points out that this is corroborated by the observations made by Mr. Brush that etherion is absorbed by phosphoric acid and soda-lime, as well as by the powdered glass from which it has been previously driven off by heat.

Interruption in Electrical Supply.—An interruption to the supply at High Wycombe on Wednesday, last week, was attended with rather amusing consequences. At 10.30 in the evening, a triple concentric feeder broke down, the neutral conductor, which formed the outer concentric ring, becoming practically short-circuited to the negative main. The effect of this was to blow the fuses at the station end of the feeder, and at the same time to melt the copper bridges at the station end of all the middle-wire feeders. As a result, the voltage on the positive side rose considerably, blowing a number of fuses, bursting some lamps and fusing some lampholders. To make matters worse, the breaking of the earth connection caused several of the fire alarms in the firemen's houses and police stations to operate. Fortunately, the central fire alarm was not affected. It must have been a disappointment to the High Wycombites that the occurrence took place on November 2nd instead of November 5th, though, perhaps, from the firemen's point of view April 1st would have been a more suitable date. It is only fair to the contractors to add that the construction of the works at Wycombe is still proceeding, and that the final arrangements of the switchboard and mains, which will preclude the possibility of a repetition of this accident, had not yet been made. The supply to nearly all the lamps was resumed a few minutes after the occurrence.

On Saturday last there was a failure of the electric light in some streets in Dublin.

The Manchester Corporation and the Telephones.—The following letter has been received by the Manchester Corporation from the Postmaster-General:—

General Post Office, London, Nov. 3, 1898.

The Postmaster-General has had under consideration the series of questions which were handed to him by the deputation from the Special Committee of the Corporation of Manchester which waited on him on the 31st ult., and has instructed me to inform you in reply that the report of the Select Committee on Telephones is now engaging the attention of Her Majesty's Government, and that until the decision of Her Majesty's Government is known it is impossible to give a definite reply to the various inquiries addressed to him. The Postmaster-General, however, directs me to add that:—

1. He has no immediate intention of establishing Post Office competition in a city like Manchester, where the Post Office has not hitherto instituted any local exchange.

Digitized by Google

2. He has no intention of conferring any licence on any private company for carrying on the business of a telephone exchange.

3. In the event of the report of the recent Select Committee being approved by Her Majesty's Government a Bill will be introduced into Parliament to give effect to its recommendations. This Bill would *inter alia* authorise the Postmaster-General to grant provisional orders to enable a local authority to lay down and work telephones in its own district or the districts of other authorities within the exchange area.

4. The Postmaster-General is not in a position at the present time to state what conditions may be inserted in the licence so granted for the purchase by the Post Office of the land, buildings, and plant, acquired by the Corporation for the purposes of the exchange. But in framing the provisions due weight will, at the right time, naturally be given to the recommendations of the Select Committee on the subject.

5. The Postmaster-General does not consider it any part of his duty to lay down the conditions on which local authorities should be allowed to borrow money for the purpose of opening a telephone exchange.

6. In the event of any licence being granted to a municipality the Postmaster-General would not propose that it should extend over an area larger than that already granted to the National Telephone Co.—Your obedient servant, S. WALPOLE.

The London County Council and the Telephone Service.—The Postmaster-General has sent the following letter to the London County Council, in reply to their inquiry whether the necessary measures were being taken for the establishment of a competing telephone service in London :—

With reference to your letter of the 14th inst., in which you state that the London County Council have had under consideration the recommendations of the Select Committee on Telephones of last session with regard to competition with the National Telephone Co., and that they are of opinion that such competition in London should be undertaken by the Post Office, I am directed by the Postmaster-General to acquaint you, for the information of the Council, that her Majesty's Government are considering the report of the Committee and that, if they adopt its suggestions, Parliament will be asked to legislate on the subject.—Yours, &c., S. WALPOLE.

In connection with this letter, the Highways Committee of the Council have now drawn up a public report in which they set out an account of the interview between a deputation of the Manchester Corporation and the Postmaster-General, to which we made reference in our last issue. They point out that it would appear, from the reply of the Postmaster-General to the Manchester deputation and from the letter from the secretary of the Post Office, that there was some doubt whether the Post Office would at once, as it had power to do, establish this competing service. It was now too late for the Council itself to ask in the ensuing session for powers to establish a London telephone service, and should the Government fail then to introduce a general Bill to enable local authorities to establish services for their respective districts, either alone or in combination, the matter would be very seriously delayed, and the period within which the local authorities could expect to recoup some portion of the outlay would be shortened, which might render it impracticable for them to undertake the service. They accordingly recommend the Council to address a letter to the Postmaster-General embodying these views on the subject and pointing out the extreme urgency of the matter, and the desirability of a decision being promptly arrived at by the Government upon the question whether the Post Office shall establish a competing telephone service. This recommendation was adopted unanimously at Tuesday's meeting of the Council.

The Liverpool Engineering Society and Electric Traction.—At the inauguration of the new session of this society, on the 3rd inst., Mr. John A. Brodie, city engineer, the newly-elected president, delivered an inaugural address dealing with some of the more important questions relative to the local transport of goods and passengers, and gave a short history of the rise and progress of traffic inland from Liverpool. He particularly referred to the recommendations contained in the report of the Committee formed by the Liverpool Chamber of Commerce with regard to the construction of a goods railway to Manchester, and, while expressing his general approval of these recommendations, he doubted whether a railway pure and simple would be likely to meet the requirements, and he believed for short distances the principle of the plateway would ultimately come to the front. If Liverpool really grasped the great importance of the issue at stake, the matter of the few hundred thousand pounds required for the construction of a metal way would not long be allowed to handicap the progress of the trade of the port of Liverpool and of Lancashire. The proposed junction of the future Liverpool electric tramway system with those of Prescot and St. Helens was interesting, as, if carried out, it would form a practically continuous line of electric tramways from the Landing Stage to the colliery district of Haydock, a distance of 15½ miles, and, if authorised, there could be little doubt that important extensions on the Lancashire side would follow. This would go far to prove whether heavy goods traffic could be safely and conveniently conveyed over ordinary tramway lines in public streets, and there could be little doubt on this head when it was considered that the present horse tramway traffic passing over the single line in front of the Town Hall represented a weight of vehicles and passengers of approximately 4,000 tons a day, or 1,500,000 tons per annum, and that the same number of electric trams would mean a weight of not less than 11,000 tons per day, or 4,000,000 tons per annum. On the question of motor cars, he pointed out the developments that were likely to accrue in the direction of heavy motor-waggon traffic. There should be a considerable opening for a motor vehicle in the sweeping and collection of dust and the street watering, and he was satisfied that where the length of cartage exceeded two miles the cost of conveyance, including all proper charges, would be considerably below that of horse cartage. Referring to the tramways traction and the various forms of mechanical traction on the market, he said that the surface contact system could hardly be said to be beyond the experimental stage though giving considerable promise. Comparing the advantages of the overhead trolley and conduit system, he said there could be no question of the superiority of the first-named from all points of view except that of appearance. It was in the centres of large towns, if anywhere, that the heavy additional expense of a well-constructed conduit was warranted, and, where it was decided upon, the design should be of ample dimensions and the construction of the most substantial character. The conduit system involved delays for special parts and much more interference with street traffic during construction than the trolley system, especially in narrow streets, and the experience of Berlin, where electric cars were being run by accumulators over well-constructed conduit lines, should not be lost sight of. In the matter of electric tramways we had lagged ten years behind our more enterprising American and Continental engineers, and we could not legitimately grumble if we found that those countries which had spent their money in experiments and done hard pioneer work, now stepped in to equip our lines with materials that could not be obtained at home in sufficient quantity to meet requirements.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, November 11th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda :—(1) Discussion on Mr. A. Campbell's Paper on "The Magnetic Fluxes in Meters and other Electrical Instruments"; (2) "On the Propagation of Damped Electrical Oscillations along Parallel Wires," by Prof. W. B. Morton; (3) "On the Properties of Liquid Mixtures," by R. A. Lehfeldt.

TUESDAY, November 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion :—"Electrical Transmission of Power in Mining," by W. B. Esson.

WEDNESDAY, November 16th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Annual General Meeting of the Students' Section in the Library of the Institution.

ROYAL MICROSCOPICAL SOCIETY.

7:30 p.m. Ordinary Meeting at 20, Hanover-square, W.

SOCIETY OF ARTS.

8 p.m. The Opening Address of the Session will be delivered by Sir John Wolfe Barry, F.R.S., on "Internal Traffic of London."

FRIDAY, November 18th.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:30 p.m. Second General Meeting of the Session in the Literary and Philosophical Society's Lecture Hall, Newcastle-on-Tyne. Paper to be read :—"Repairs to Iron and Steel Vessels in way of Boilers and Stokeholes," by M. W. Aisbitt.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting, when the following Paper will be read :—"Liquid Air: A Short Description of its Production and Summary of its Application to the Chemical or other Industries," by Cecil Lightfoot.

THE FOLKESTONE ELECTRICITY SUPPLY WORKS.

As in most provincial towns, the question of electric lighting was raised in Folkestone some 13 or 14 years ago, and it met with considerable opposition, especially from those members of the Corporation who happened to be shareholders in the local gas company. Since then several schemes were considered by the Corporation, including one for a combined electric light and dust destructor; but none of these obtained general approval, and finally in November last year the Provisional Order, acquired by the Corporation in 1896, was transferred to the Folkestone Electricity Supply Co. The contractors for the whole of the plant were Edmundson's Electricity Corporation, who have, we believe, a considerable interest in the Company, there being also a number of local shareholders. The capital of the Company is £50,000. The first sod at the works was not cut until the first week in February, but yet by March 27th a supply from plant, part of which was temporary, was given to an important consumer, and a general supply for private lighting was commenced by July 1st. On the occasion of the inaugural ceremony, referred to in our last issue, the public arc lighting was started, the station being nearly complete. The present lamp connection is 24 arcs and the equivalent of 9,000 8 c.p. incandescent lamps.

Considerable difficulty was experienced in securing a site for the central station, and, finally, one had to be taken at over a mile from the centre of the town. The position is seen from Fig. 1. As regards coal supply, the station is placed very conveniently; but, of course, its outside situation must have its effect on the economy of distribution. The land, as is most of the newer part of Folkestone, was the property of Lord Radnor, and it was at his suggestion that the elegant chimney, seen in Fig. 2, was built more or less in imitation of Messrs. Doulton's in Lambeth. Coal is delivered from a private siding by the Shorncliffe station of the South-Eastern Railway, straight into the coal bunkers. These have a capacity of about 150 tons, and are placed close to the boilers, as seen in Fig. 3, being fitted with a movable front to allow of the boiler tubes being draw for repairs. The Company owns 1½ acres of ground, so that there is ample room to extend the buildings.

The buildings were erected by Mr. D. Baker, of Folkestone, under the supervision of Mr. Reginald Pope, the architect. Their arrangement is clearly shown in Figs. 2 and 3. They are entirely of fireproof material, the roof being constructed of steel, slate and glass. The slates are fastened to the angle iron purlins by lead clips, and expanded steel lathing, plastered, is attached to the inside of the engine-room roof. The cast iron water tank over the coal bunkers has a capacity of 17,500 gallons. The chimney is 150ft. high, and its area at the narrowest part is 49 sq. ft.; it is lined with firebrick to about 50ft. It is interesting to note that the chimney was built from the inside, an electric motor being employed to drive the winch (through ordinary belting and friction gear) used for lifting the workmen and the materials.

The boiler-house (Fig. 4) is at present equipped with three boilers of Messrs. Davey-Paxman's "Economic" type, 14ft. long by 8ft. diameter. There is space left in the boiler-house for two more of similar size if required. Each of the boilers is

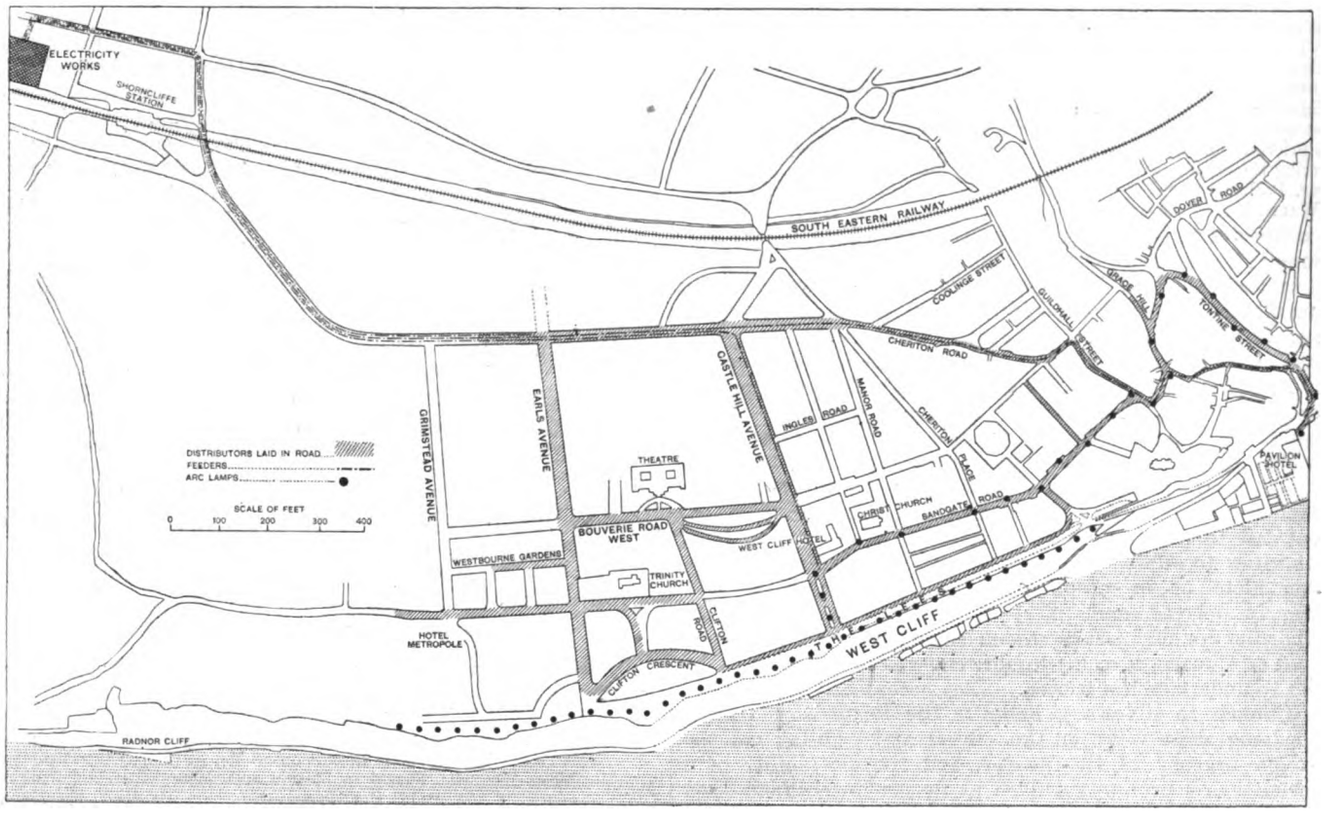

FIG. 1.—Map of District, showing Position of Electric Supply Station and Mains.

capable of evaporating 6,000lb. of water per hour at 150lb. pressure. Two of the boilers, which were used for a time with a temporary chimney, are fitted with Meldrum forced-draught furnaces. No economiser has been put in at present, but space has been left in case one is desired later. The contractors doubt, however, whether an economiser would be of much use with this type of boiler and a feed heater. Water is at present obtained from the town mains, but a 7½in. steel tube well is being sunk to a depth of 180ft., from which sufficient water will be supplied. As the water is very hard an exhaust "heater detartoriser" of Mr. William Boby's make is employed. This is capable of dealing with 12,000lb. of water per hour. The water enters at the top and flows downwards till it reaches the suction pipe of the feed pumps, which it enters at a boiling temperature. The apparatus consists of a number of circular trays set one upon another so as to form a column. Each tray is always nearly full of water, and the exhaust steam from the engines, entering near the bottom of the apparatus, bubbles through the water, raising it to boiling temperature, while the amount of back

Digitized by Google

pressure caused in the exhaust pipe is said to amount only to a few inches on the water gauge. The heating of the water causes the carbonates of lime to be deposited, and the sulphates are dealt with by means of a small quantity of

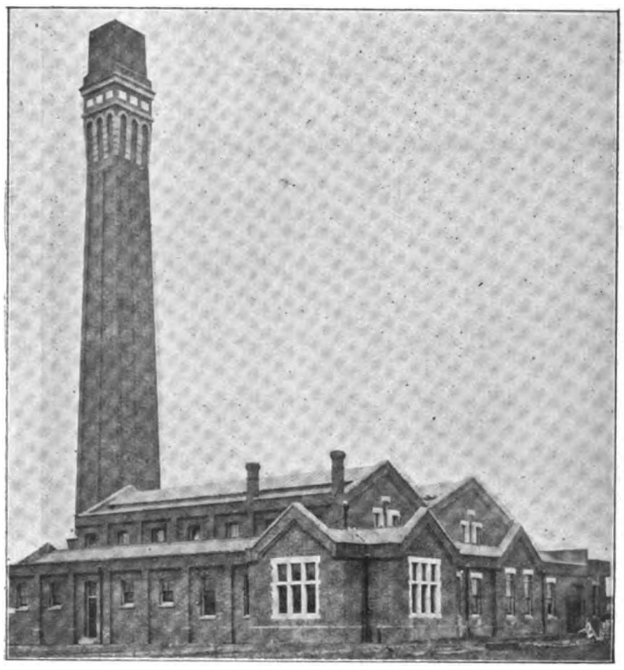

FIG. 2.—External View of Supply Station.

common soda solution, which is automatically injected at the top of the detartoriser, in exact proportion to the amount of water passing through the machine. No attempt is made to remove the sediment by blowing out, but when cleaning is required the trays are lifted down and cleaned—a by no means lengthy operation, as the deposit, though compact, is soft. As there is practically no pressure in any part of the apparatus when at work, the joints are made by the weight of the parts without bolting, by simply employing ordinary glazier's putty. The apparatus is stated to reduce the hardness of the water to not exceeding three grains per gallon, and it possesses the advantage that its efficiency as a heater does not diminish as load is added to the plant.

Up to last week Worthington centrifugal feed-pumps were used as a temporary expedient, but these have now been replaced by two three-throw pumps with gun-metal plungers, made by Messrs. Hayward, Tyler and Co., driven by Parker two-polar shunt motors. The pumps will deliver 12,000lb. of water per hour when running at 43 revolutions per minute, this low speed being attained by the use of double-reduction gear with raw-hide teeth to the pinions. Switching apparatus is provided to allow a supply of 210 or 420 volts, thus giving two speeds, and further regulation of the speed is obtained by inserting resistance in the field and armature circuits of the motors. The feed piping is arranged in duplicate with two connections to each boiler, with the requisite number of Hopkinson's valves to isolate any pump or any portion of the piping in case of failure. The pumps can either be supplied with cold water from the supply tank or with hot water from the feed heater.

The usual ring main system is used to supply the engines. The mains are of 7in. steel with copper bends, with 5in. steel connections to the boiler and 2½in. and 3½in. copper connections to the engines. The main piping is drained at the ends of the ring to Geipel steam traps, and connections for drains are also fitted at the foot of the separators on the engine beds to similar drains. Steam being continually connected to these separators, dry steam is always available for starting up any engine.

A good view of the engine room is given in Fig. 4. Three generating sets are installed up to the present, one of 246 B.H.P. and the other two 120 B.H.P., when running at 375 and 480 revolutions per minute respectively, with steam at 140lb. at the stop valve. A second engine of the larger size is on order and is expected to be in place by the end of the year. All are of the Peache type coupled to Parker dynamos. They are single-acting three-crank six-cylinder engines, and they were running very silently at the time of our inspection. There appears to be nothing exceptional in the construction of the dynamos. They are of Messrs. Parker's two pole type with steel magnets and Eickemeyer windings. They are designed to give from 420 to 460 volts pressure, and to be connected across the outers of the three-wire system; the smaller ones give 160 amperes, and the larger ones 380 amperes. The booster and balancer set is also of Messrs. Parker's make. There is an eight-ton overhead crane travelling the whole length of the engine room.

Two views of the switchboard are given in Figs. 6 and 7. It is made of enamelled slate supported on a steel frame with a wooden moulding round the edge. The greater part of the

Digitized by Google

woodwork seen in Fig. 6 is shortly to be removed. As usual the three panels are for each of the three wires. The feeders are brought in at the top of the board through double-pole fuses to the ammeters and thence to the alternate vertical bars shown in Fig. 7. The dynamos are connected, on one side through Siemens minimum cut-outs (shown merely as rectangles in Fig. 7), and on the other side through ammeters, to the remaining four pairs of vertical bars, and the connections are made through three 'bus bars at the back of the board by means of brass plugs screwed into the holes by a special key. On the left-hand panel are the rheostats for the field circuits. As already stated, the dynamos are not directly connected to the central panel of the board, to which the middle wire of the feeders, the centre cells of the storage battery, and the "booster" connections are brought. On this panel is a 14-way regulating switch for each side of the battery, and a throw-over switch, by means of which the cells are connected either directly to the 'bus bars or to the armature of the booster. Two other throw-over switches are provided for the purpose of exciting the field of the boosters and short-circuiting them immediately the circuit is broken, thereby preventing an abnormal rise of pressure in their windings. The remaining double-pole switch is for starting the balancer, and it is interlocked with a resistance switch. On the upper part of this panel are the battery ammeters, the middle-wire ammeters, and the zero indicators for putting the dynamos or boosters in parallel. These zero indicators, which are of the Kelvin type, made by Mr. James White, are really low-reading voltmeters, but they are designed to withstand high pressures, and have their zeros in the middle of the scale. They are connected to the poles of the switch it is desired to close, and when the indication is zero it is known that the two machines are at the same pressure, and the attendant can close the switch. This forms a very simple and effective method of paralleling. The ammeters are all Lord Kelvin's sector pattern ampere gauges, likewise supplied by Mr. James White, who also furnished the voltmeters. The switchboard was made by Mr. Edmund Charrington to Messrs. Edmundson's design.

It will have been noticed that, with the exception of the zero indicators, there are no voltmeters on the switchboard. The only voltmeters employed are those seen on the left hand wall of the engine room in Fig. 5. They are electro-static voltmeters of the standard Kelvin engine room type and are connected at the ends of the pilot wires from the feeding points. The large open scales are visible from every part of the engine room. Thomson-Houston meters are fitted on each dynamo circuit, and Aron meters with Miller's single dial attachment are used for the accumulators. These latter are 230 cells of the D.P. type in glass boxes erected on wooden stands in two tiers. They are guaranteed to give a discharge of 80 amperes for nine hours or 119 amperes for four hours.

The supply is at 210 volts at the consumers' lamps, and the arc lamps are connected in series of eight across the 420 volt mains. Owing to the distance of the station from the centre of the supply area the feeders and distribution mains are a very important feature of the system. The whole of the network has been supplied by Messrs. Callender's, the cables being insulated with impregnated jute, lead-covered and armoured, and laid directly in the ground. Tarred boards are laid over them for protection from workmen who may be making excavations in the neighbourhood at some future time. The feeders are triple concentric with heavy lead-covering and steel-tape armouring, being connected to the distributing network at large feeder boxes. The configuration of the network is clearly shown in Fig. 1. The pilot wires are three-core, lead-sheathed, steel-taped cables laid in the same trench as the feeders. Three core, in preference to triple concentric cables, has also been used for the distributors owing to its convenience for connecting the house services. It may be mentioned that there are a number of Callender's standard type of network boxes fixed at the junctions, and so constructed that it is a simple matter to disconnect the mains at different sections for testing purposes. The feeders are in two sizes; 0·2 sq. in. and 0·4 sq. in. in area respectively. The section of the third wire is half that of the others. The largest distributors are of 0·1 sq. in. sectional area, their third wires being of 0·06 sq. in. Each of the wires of the three-core pilot cables have a sectional area of 0·008 sq. in. Sixty-eight arc lamps of Messrs. Johnson and Phillips' make are being erected at present. They take a current of 10 amperes and burn for 14 hours with single carbons. On each post are two incandescent lamps of 25 c.p. for use after 11:30 p.m. The circuits of the arc and incandescent lamps are connected to main circuits tapped from the network boxes by means of four-core non-hygroscopic cable, which is lead-sheathed and steel-armoured, two of these wires being for the arc lamps and two for the incandescent. The designs of the posts selected by the Corporation have very small chambers in their bases, so that there is only room for the isolating switches and substitutional resistances in them. The circuit switches and resistances are contained in pillar boxes similar in appearance to those frequently used for the line switches of a tramway system. There are five of these switch pillars, each arranged for three circuits.

Mr. J. C. Wigham has superintended the work on behalf of Messrs. Edmundson's, and Messrs. Lacey, Clirehugh and Sillar advised the Folkestone Company upon the contract and supervised the execution of the work on its behalf. Mr. Thomas Hesketh was the resident engineer for Messrs. Edmundson's, and his services have now been secured by the Folkestone Company as their engineer and manager.

CURRENTS IN BRANCHED AND IN MUTUALLY INDUCING CIRCUITS PRODUCED BY HARMONICALLY VARYING ELECTROMOTIVE FORCES.

(*Continued from page 818, Vol. XLI.*)

BY PROF. THOMAS R. LYLE.

I will now give a few examples of the application of the foregoing principles to alternate current problems.

Example I.—The Transformer.

Let $R_1L_1C_1E$ refer to the primary circuit, $R_2L_2C_2$ to the secondary, and let M be the coefficient of mutual induction. Applying Kirchhoff's extended laws, we get

$$E + mC_2 = r_1C_1,$$
$$mC_1 = r_2C_2.$$

Eliminating C_2, we have

$$E = \left(r_1 - \frac{m^2}{r_2}\right)C_1, \text{ or } E = r_1'C_1,$$

which shows that the primary current is the same as if the secondary coil were absent, and the constants of the primary changed to R'_1 and L'_1 where

$$R'_1 = R_1 + \frac{\omega^2M^2}{I_2^2}R_2,$$

$$L'_1 = L_1 - \frac{\omega^2M^2}{I_2^2}L_2,$$

$$(I_2^2 = R_2^2 + \omega^2L_2^2).$$

Hence if $E = e \cos \omega t$

$$C_1 = \frac{e}{I'_1}\cos(\omega t - \phi_1),$$

where $I'^2_1 = R'^2_1 + \omega^2L'^2_1$

and $\tan \phi_1 = \frac{\omega L'_1}{R'_1}$.

Since $C_1 = \frac{r_2}{m}C_2 = \frac{I_2e^{i\phi_2}}{\omega Me^{-i\pi/2}}C_2,$

where $\tan \phi_2 = \frac{\omega L_2}{R_2}$ and $I_2^2 = R_2^2 + \omega^2L_2^2$.

$$\therefore C_2 = \frac{\omega M}{I_2}e^{-i(\pi/2+\phi_2)}C_1,$$

or $$C_2 = \frac{\omega M}{I_2}\frac{e}{I'_1}\cos(\omega t - \phi_1 - \pi/2 - \phi_2).$$

$\pi/2 + \tan^{-1}\frac{\omega L_2}{R_2}$ being the difference of phase of C_1 and C_2, we

Digitized by Google

see that for light loads (R_2 large) this difference approximates to $\pi/2$, or the currents are nearly in quadrature, while for heavy loads (R_2 small) it approximates to π, or the currents are nearly in opposition. The magnetic flux B through the core being equal to $(n_1C_1+n_2C_2)\sigma$, where n_1 and n_2 are the numbers of windings and σ the flux through the core due to 10 ampere-turns, we find, since $L_1=n_1^2\sigma$, $L_2=n_2^2\sigma$ and $M=n_1n_2\sigma$ if we neglect magnetic leakage,

that
$$B=n_1\sigma\left\{1+\frac{n_2}{n_1}\frac{m}{r_2}\right\}C_1,$$
$$=n_1\sigma\left\{1-\frac{n_2}{n_1}\frac{\iota\omega M}{R_2+\iota\omega L_2}\right\}C_1,$$
$$=n_1\sigma\frac{R_2}{I_2^2}(R_2-\iota\omega L_2)\,C_1,$$

as
$$\frac{n_2}{n_1}=\frac{L_2}{M_2}\ q.p.,$$

i.e.,
$$B=n_1\sigma\frac{R_2}{I_2}e^{-\iota\phi_2}C_1,$$
$$=n_1\sigma\frac{R_2}{I_2}\frac{e}{I'_1}\cos(\omega t-\phi_1-\phi_2),$$

where $\tan\phi_2$ as before $=\dfrac{\omega L_2}{R_2}$.

From the above expressions for C_1 C_2 and B the behaviour of the transformer under varying conditions can be immediately deduced.

The power drawn from the mains being the average value of EC_1, that is, $\frac{1}{2}ec\cos\phi_1$ is
$$=\tfrac{1}{2}e^2\frac{R'_1}{I'_1{}^2}.$$

The power supplied to the external secondary circuit being the average value of $S'C_2^2$, that is $\frac{1}{2}S'c^2$ (where S′ is the external resistance of the secondary, S being the internal and $R_2=S+S'$), is equal to
$$\tfrac{1}{2}S'\frac{\omega^2M^2}{I_2^2I'_1{}^2}e_2.$$

The efficiency of the transformer is therefore
$$\frac{S_1}{R'_1}\frac{\omega^2M_2}{I_2^2},$$
which is a maximum (S′ variable) when
$$S'^2=S^2+\omega^2L_2{}^2+\frac{S}{R_1}\omega^2M^2,$$
and the maximum value is
$$\frac{1}{1+2\dfrac{R_1R_2}{\omega^2M^2}}.$$

The values of the currents and of the powers drawn from the mains and supplied by the transformer can, for the case of maximum efficiency, be at once got by substituting in the expressions for these quantities the corresponding value of R_2, that is, $S+\sqrt{S^2+\omega^2L_2{}^2+\dfrac{S}{R_1}\omega^2M^2}$.

In the simple case, when the internal resistance S is neglected, R_2 for max. efficiency $=\omega L_2$, and if we assume in addition $M^2=L_1L_2$,
$$C_1=\sqrt{2}\frac{e}{\sqrt{R_1^2+(R_1+\omega L_1)^2}}\cos(\omega t-\phi_1),$$
where $\tan\phi_1=\dfrac{\omega L_1}{2R_1+\omega L_1}$,
$$C_2=\frac{M}{L_2}\frac{e}{\sqrt{R_1^2+(R_1+\omega L_1)^2}}\cos\left(\omega t-\phi_1-\frac{3\pi}{4}\right),$$
$$B=n_1\sigma\frac{e}{\sqrt{R_1^2+(R_1+\omega L_1)^2}}\cos\left(\omega t-\phi_1-\frac{\pi}{4}\right).$$

Power drawn from mains
$$=\tfrac{1}{2}\frac{R_1+(R_1+\omega L_1)}{R_1^2+(R_1+\omega L_1)^2}e^2.$$

Power supplied by transformer
$$=\tfrac{1}{2}\frac{\omega L_1}{R_1^2+(R_1+\omega L_1)^2}e^2.$$

It is also worth pointing out that if $R_2=0$,
$$C_1=\frac{e}{R_1}\cos\omega t,$$
and if $R_2=\infty$,
$$C_1=\frac{e}{I_1}\cos(\omega t-\phi_1).$$

In the case of a transformer supplying power there will be inductance in the external secondary circuit, and the formulæ applying to this case can be at once got from those already established {when L_1L_2 is not $=M^2$} by substituting $L_2+L'_2$ for L_2, where L_2 now represents the internal and L'_2 the external inductance of the secondary. The effect on the action of the transformer of varying L'_2 can be at once deduced, and an interesting case is presented when L'_2 becomes negative, that is, when capacity predominates in the external secondary circuit.

All the discussion already given about a transformer treats of the case when the energy supplied is at constant pressure, but an obvious modification of the results already obtained will make them apply to the case of a constant current supply.

I will now give an example on the general theory of the transformer, having inductance (or capacity) in its external secondary circuit, taking account of leakage and hysteresis when the impressed E.M.F. is harmonic and of constant amplitude, and assuming that the forced variations of the other quantities are also harmonic. If we represent by a vector (M, say) in the diagram the magnetomotive force applied to any iron circuit, then the resulting magnetic flux N will not, on account of hysteresis and Foucault currents, be in phase with M, but will lag behind it, and will be, from the same causes, slightly diminished in amplitude, so that the

vector equation
$$N=\kappa e^{-\iota\theta}\frac{M}{p},$$

(where p is the magnetic reluctance of the circuit, κ a number very little less than unity, and θ a small angle generally) will represent very approximately the relation between M and N. Now, if n_1 and n_2 be the primary and secondary turns, σ_{11} the magnetic flux through the primary due to 10 ampere-turns of the primary, σ_{22} a similar quantity for the secondary, and σ_{12} the magnetic flux through the secondary due to 10 ampere-turns of the primary ($\sigma_{12}=\sigma_{21}$), N_1 and N_2 fluxes through primary and secondary, then

(I.)
$$N_1=\kappa e^{-\iota\theta}(n_1\sigma_{11}C_1+n_2\sigma_{12}C_2),$$
$$N_2=\kappa e^{-\iota\theta}(n_1\sigma_{12}C_1+n_2\sigma_{22}C_2),$$

C_1 and C_2 being the primary and secondary currents (vectors on the diagram). But

(II.)
$$E-n_1\frac{dN_1}{dt}=R_1C_1,$$
$$-n_2\frac{dN_2}{dt}=(R_2+\iota\omega L'_2)C_2,$$

where L'_2 is the external inductance of secondary, and remembering that if any vector V on the diagram represent

$v\cos\omega t$, $\quad -\dfrac{dv}{dt}=r\omega\cos\left(\omega t-\dfrac{\pi}{2}\right)=\omega e^{-\iota\frac{\pi}{2}}V.$

Hence, substituting from I. into II., we get

$$E+\kappa n_1\omega e^{-\iota\left(\frac{\pi}{2}+\theta\right)}(n_1\sigma_1C_1+n_2\sigma_{12}C_2)=R_1C_1,$$
$$\kappa n_2\omega e^{-\iota\left(\frac{\pi}{2}+\theta\right)}(n_1\sigma_{12}C_1+n_2\sigma_{12}C_2)=R_2+\iota\omega L'_2)C_2, \quad \text{or}$$

(III.)
$$E+mC_2r_1=C_1,$$
$$mC_1r=C_2,$$

where if we put $\kappa n_1{}^2\sigma_{11}=L_1$, $\kappa n_2{}^2\sigma_{22}=L_2$, and $\kappa n_1n_2\sigma_{12}=M$,
$$r_1=R_1+L_1\sin\theta+\omega L_1\cos\theta,$$
$$r_2=R_2+\omega L_2\sin\theta+\omega(L_2\cos\theta+L_2{}^1),$$
$$m=\omega Me^{-\iota\left(\frac{\pi}{2}+\theta\right)}.$$

Digitized by Google

So that this general case of the transformer is reduced practically to the simple case solved in Example I.

Eliminating C_2 from equations III. we get (as in Example I.),

$$E = \left(r_1 - \frac{m^2}{r_2}\right)C_1,$$

showing that the current in the primary is the same as if the secondary were removed and the constants of the primary changed to ρ and λ where

$$\rho = R_1 + \omega L_1 \sin\theta + \frac{\omega^2 M^2}{I_2^2}\{R_2 \cos 2\theta - \omega L'_2 \sin 2\theta - \omega L_2 \sin\theta\},$$

$$\omega\lambda = \omega L_1 \cos\theta - \frac{\omega^2 M^2}{I_2^2}\{\omega L_2 \cos\theta + \omega L'_2 \cos 2\theta + R_2 \sin 2\theta\},$$

where $I_2^2 = (R_2 + \omega L_2 \sin\theta)^2 + \omega^2(L_2 \cos\theta + L'_2)^2$.

Hence, if $E = e\cos\omega t$,

$$C_1 = \frac{e}{I}\cos(\omega t - \phi_1)$$

where $I^2 = \rho^2 + \omega^2\lambda^2$; and $\tan\phi_1 = \frac{\omega\lambda}{\rho}$.

Again, as $C_2 = \frac{m}{r_2}C_1$, we find at once,

$$C_2 = \frac{\omega M}{I_2}\frac{e}{I}\cos\left(\omega t - \phi_1 - \frac{\pi}{2} - \theta - \phi_2\right),$$

where $\tan\phi_2 = \omega\frac{L_2\cos\theta + L'_2}{R_2 + \omega L_2 \sin\theta}$.

From the above values for C_1 and C_2 any quantity involved in the theory of the transformer can be at once obtained, and with a slight modification, the above theory may be made to apply to a constant current transformer. L'_2 may be positive or negative.

As in Example I., the power drawn from the mains, the power supplied to the external secondary circuit, the copper losses per second in primary and secondary, and the efficiency can be at once written down.

The power absorbed by hysteresis and Foucault currents will be found to be equal to

$$\frac{1}{2}\frac{e^2}{I^2 I_2^2}\omega\sin\theta[L_1(R_2^2 + \omega^2 L'^2_2) + \omega(L_1L_2 - M^2)(\omega L_2 + 2R_2\sin\theta + 2\omega L'_2\cos\theta)],$$

in which the term in $L_1L_2 - M^2$ represents the loss due to hysteresis, &c., of the lost or leaked magnetic lines, while the other term represents that due to the hysteresis, &c., of the lines looped on both primary and secondary circuits.

It must be remembered that L_1L_2 and M are not the inductance coefficients of the coils as usually understood, but κ times them where κ (the hysteresis amplitude factor) is a number slightly less than unity. The amplitude of the flux actually produced by a given current is the same as if κ were taken = 1, and the permeability of the iron diminished in the ratio $1:\kappa$.

If a coil n turns per centimetre is wound on a long rod of iron of unit cross-section, and of permeability μ, then $H = 4\pi nC$ where C is the current $= c\cos\omega t$ in the coil. B, therefore, if harmonic, $= \mu\kappa e^{-i\theta}H = 4\pi n\mu\kappa c\cos(\omega t - \theta)$, but at any instant the back E.M.F. per centimetre of the rod is

$$n\frac{dB}{dt} = n\omega e^{i\frac{\pi}{2}}B = 4\pi n^2\omega\mu\kappa c\cos\left(\omega t - \theta + \frac{\pi}{2}\right),$$

hence the power absorbed per cubic centimetre of the iron of the rod, being the average value of $nC\frac{dB}{dt}$, is $4\pi n^2\omega\mu\kappa c^2\sin\theta$, or $2\nu n^2c^2\mu\kappa\sin\theta$, where ν is the number of alternations per second ($\omega = 2\pi\nu$).

Hence the work done per alternation per cubic centimetre

$$= 2n^2c^2\mu\kappa\sin\theta,$$

$$= \frac{h^2}{8\pi^2}\mu\kappa\sin\theta,$$

where h is the amplitude of the magnetising force. As this hysteresis loss can be determined for any sample of iron $\kappa\sin\theta$ can be found, and as κ is very nearly unity, $\sin\theta$ can be found to the first order. The preceding discussion involves the assumption that if C be harmonic so will be B. This is not a correct assumption, but the result arrived at will be a fair approximation to the truth.

(To be concluded.)

ELECTRICITY WORKS ACCOUNTS.

Ayr Municipal Electric Supply Works.

Municipal electric supply in Ayr was commenced on January 8, 1896, so that the first of our tables this week refers to the two completed years of working. The authorised capital is £40,000, and the received capital £40,827, borrowed at 3 per cent. A sum of £1,750 has been repaid, and £36,920 expended, representing £59 per kilowatt capacity of generating plant installed. We are unable to give the separate items of capital expenditure, as they are not rendered in the accounts issued.

Last year's output was 161,093 units sold, showing an increase of about 29 per cent. over that of the previous year; the accruing revenue was £2,445 being an average price of 3·64d. per unit. A great improvement has been made in the ratio of the costs to the revenue in that by a reduction in the total costs per unit of 0·88d. this ratio has been reduced from 105 per cent. to 80·4 per cent. All the items of cost, except that of wages at the station, have fairly contributed to this satisfactory economy, which has resulted in a working profit of £478 being made. £581 has been paid into the Sinking Fund, and £1,052 as interest on loans, resulting in a deficit of £1,155, which has been carried to the police account, to be met by the rates.

Walsall Municipal Electric Supply Works.

Our second table covers the accounts of the two completed years of working of the Walsall undertaking. The authorised capital stands at £23,400, of which £21,500 has been received, borrowed at 3 per cent.

The expenditure to capital account at Dec. 31 last had reached £20,959, representing £87. 6s. per kilowatt of generating plant in the station.

Last year saw 24 additional consumers and an equivalent of 1,900 8 c.p. lamps connected to the mains. The output was 96,376 units sold, representing an increase of about 44 per cent. over the output for 1896. As a result of the introduction of the maximum demand system of charging, with 2d. per unit charge after 1½ hours, the average price per unit sold has dropped from 5·6d. to 5·1d. The total costs per unit have been reduced by 0·3d. through a reduction in the management and property charges; works costs have remained steady.

The financial results are a working profit of £547, a payment of £524 towards redemption of stock issued, and £555 interest, leaving a deficit which, with that of the previous year, amounts to £977.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared :—

Bedford (Municipal)	Mar. 4	Kensington & Knightsbridge (Co.)	Sept. 30

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	15s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trembley Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I. Price** 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. **VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS.** New Edition. Price 12s. 6d., post free. **VOL. II.—THE UTILISATION OF INDUCED CURRENTS.** Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 8d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

'THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

SHAFTING *VERSUS* DIRECT-DRIVING.

The Paper recently read by Mr. Langdon before the Institution of Mechanical Engineers has once again brought to the front the vexed question of large motors and shafting *versus* separate motors for each machine in connection with the electrical transmission of power in works. The Paper also, of course, raised the whole question of the advantages of electricity as a motive power; but with this we do not here propose to deal, further than by once again pointing out that, where a number of shops have to be driven, there can be no question of the advisability of employing electricity distributed from a single efficient centre, in place of long lines of shafting, or of a number of separate engines with numerous boilers or long steam pipes. Granted the employment of electricity as the means of bringing power to a shop, we propose to discuss the merits of the two possible methods of distributing the power in the shop itself.

Mr. Langdon has shown us that in the case he was dealing with 72 per cent. of the energy supplied to the main shafting was lost in transmission to the work on the machine-tools, and in the discussion on the Paper it was made clear that losses of this magnitude were of frequent occurrence. *Primâ facie*, therefore, there would seem to be a great gain in using motors coupled direct to the machines. But it must be remembered that loss of energy in itself is no bad thing; it is the cost of the loss that is objectionable, and if by the employment of direct-driving motors the interest, &c., on increased capital expenditure amounts to more than the cost of the energy lost in shafting, then it will be economy to put up with the loss. Let us take the figures Mr. Langdon gives. With all the 15 machines at work the loss in transmission was 1,778 watts, or 2·4 H.P., which at £10 per horse-power gives a loss of £24 per annum. But this does not include the loss in the driving motor, which at 80 per cent. efficiency would bring the loss up to £32 per annum. On the other hand, employing separate motors at, say, 50 per cent. efficiency, including the loss in the driven tool, the loss of energy would be at the rate of about 1 H.P., representing £10 per annum. Owing, however, to the fact that the

Digitized by Google

machines would, on the average, be idle during one-third of each working day, during which time current could be switched off if separate motors were employed, we must, for purposes of comparison, reduce the £10 to £7. On the other hand, the extra cost of fitting the 15 machines with their own motors would be roughly £200, and allowing 5 per cent. interest and 10 per cent. depreciation on this sum, we arrive at £30, which, together with £7, makes £37 per annum. Thus, by the use of shafting, and in spite of its low efficiency, there would be a net gain of £5 per annum. But this is not all. The motors required for separate driving would be of very small size (½ H.P. and less), running at speeds over 1,000 revolutions per minute, and such small motors give much trouble from brushes, &c.; and their number being great the total attention required would be considerable. On the whole, then, we may say that in those shops in which the machines are all small it will be advisable to adopt larger motors driving shafting. Since, however, a motor becomes much cheaper per horse-power as its size increases—a 5 H.P. motor, for instance, costing approximately but three times one of ½ H.P.—a point is reached at which it becomes economical to employ a single motor driving a group of tools through a single short line of shafting. Just exactly where this point occurs is a matter for consideration in each individual case, but as a general rule we would suggest that something like 5 H.P. will be found a suitable unit. By the employment of such units counter-shafting, with its attendant losses, could be done away with, and the tools might be so grouped that when the shop happened to be slack whole units could be cut out, and the loss from running idle saved.

The above remarks, however, only apply to a case such as that taken by Mr. LANGDON, in which a number of small machines have to be driven. In a large shop, with heavy tools, it would undoubtedly be more economical in power to do away with shafting altogether. Each machine, being of large size, would then be equivalent to one of the groups above mentioned; and as large machines have to stand idle during longer periods than small ones, owing to the difficulty of getting the work into position, and to the fact that large work is scarcer than small, the gain by cutting off power altogether except just when wanted would be very marked. Further, the saving effected in other ways by driving each machine separately would be very great. In the first place, being self-contained, machines having separate motors can be placed in such positions relatively to one another that the foreman can keep his eye on all or most of his men at once; and a machine can be moved about just as it may be desired. Secondly, owing to this flexibility of the system, drilling and other tools may be brought up to heavy castings, instead of the castings being taken to them, and with great difficulty fixed in position. Indeed, two or more tools may be brought to work upon the same casting at one time. Thirdly, the speed of the motor can be very easily and delicately adjusted to suit the work in hand; and, if desired, the speed of all the machines can be increased with very little trouble. In addition to this, the absence of belting makes the installation of overhead travellers and cranes a very simple matter, and in such machines and many others, two or three separate motors may be employed to work the various motions. Last, though by no means least, the employment of a number of motors makes the stoppage of a whole shop of very unlikely occurrence. In one or two cases it may, however, be advisable to employ a single motor and shafting; as, for instance, where two or more wall-planers are to be driven, which require an extra amount of energy at a certain portion of the stroke. It will be extremely unlikely that all the planers will require the maximum energy at one and the same time, and consequently the size of the single motor may be reduced and a saving so effected. On the other hand this principle must not be carried very far, or the great loss in the shafting will again necessitate a large motor; and though it is true that a large motor is cheaper than a number of little ones of equivalent power, there still remains the prohibitive loss of energy in the shafting.

The result we arrive at, then, is that machine tools should be grouped into units when small, and separately driven when large, and yet that this principle must not be applied too rigidly. Often it will be advisable to drive small machines (such, for instance, as winding lathes) separately, each by its own motor, for the sake of compactness; while, as we have seen in the case of wall-planers, it may be best here and there to employ short lengths of shafting even in shops for heavy work. But the present state of chaos, in which we find every combination of motor and shafting used without rhyme or reason, certainly ought to be brought to an end. The question of the arrangement to be adopted is entirely one of principle, and that principle should be fully understood before the plant is laid down. It will, of course, be said that much of the present haphazard work is due to the fact that most shops now fitted with electrical power were originally driven by steam, and that the best has been done under the circumstances; but we think that where it is considered profitable to introduce electricity at all, it will in the long run be found more economical still once and for all to apply it in the most satisfactory manner. On the other hand, the rage for very small motors exhibited by some people in their enthusiasm for electric working, and nothing but electric working, we hold to be a mistake. At present, at least, the small continuous-current motor with its troublesome commutator and more or less exposed cotton-covered wire is not suitable for the knockabout work of the shops; and though in these respects the polyphase motor has the advantage, yet, when of small size, its speed cannot be easily and efficiently regulated. This difficulty has been met in some cases by employing two tri-phase circuits of different frequency, on to either of which the motor can be switched; but even with this complication the regulation cannot be called satisfactory. A gradual variation of speed over a considerable range is what is required. But the whole question of separate driving *versus* shafting concerns only the small motor; with large machine tools there can be little doubt that separate motors ought to be employed.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

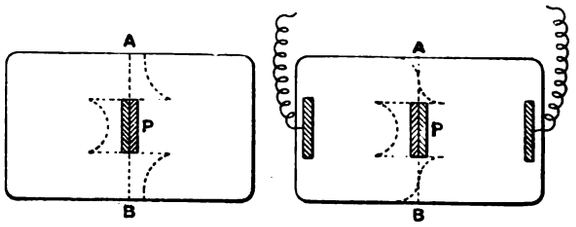
Continuity of Wave Theories.—Lord Kelvin's fascinating communication to the British Association, at Bristol, which has just been published, throws a flood of light on the connections which exist between all types of wave motion, from those of sound to Hertzian and heat waves, and to luminous and ultra-violet waves. Lord Kelvin pictures an ideally rigid globe of solid platinum of 12cm. diameter, hung inside an ideal rigid massless spherical shell of 13cm. internal diameter, and of any convenient thickness. This shell is hung in air or under water by a very long cord, or is embedded in a great block of glass, or rock, or other elastic solid. By proper application of force between the shell and the nucleus the two are made to vibrate in opposite directions with a simple harmonic motion, and an amplitude of, say, 10^{-3}cm. If the shell is in air, and the period 32 vibrations per second, a humming sound will be heard, audible to an ear a short distance away. On increasing the frequency the loudness will increase eventually to an intolerable shriek. Maintaining the same expenditure of energy, and increasing the frequency to 500×10^{12},

Digitized by Google

there will be no sound, but from all points of view not in the line of vibration a luminous point of homogeneous yellow polarised light will be seen proceeding, as it were, from the centre of the sphere. If the ether is absolutely incompressible no condensational-rarefactional waves will be sent out beyond frequencies of 4×10^{12}, and only the distortional waves will remain. Lord Kelvin points out two other lines along which such a transition may be looked for. In one of them oscillatory rotations are imparted to the sphere and the shell in opposite directions, and in the third the massless shell is replaced by an infinitely massive shell, and the platinum sphere by an electrified non-conductor. But for these the reader should study the original Paper.

[KELVIN, *Phil. Mag.*, November, 1898.]

Intermediate Conductors.—J. Stark has devised an elegant method of representing the occurrences at the surface of a metallic plate immersed in an electrolyte through which an electric current is passing. In the accompanying illustrations (*see* diagram) P represents a double plate, consisting of two different metals joined together. They form, of course, a closed circuit, and a current circulates from one to the other through the liquid. The path being shortest just round the edges the current is strongest there. The strength and direction of the current at any point in the plane A B may be represented by an ordinate on that plane. In Fig. 1 the double plate alone is active, and the current intensity at the edges is well illustrated by the dotted curves. In Fig. 2 a feeble current from the electrodes interferes with the current due to the double plate, and where the curves intersect the



plane A B there is no current at all. Almost any distribution of current may thus be brought about. A single plate of any metal is practically equivalent to a double plate, since it immediately takes a metallic deposit from the anode on passing the current. A beautiful gradation of zinc-copper alloys may be thus produced.

[STARK, *Wied. Ann.*, No. 10, 1898.]

Potential Gradients in Vacuum Tubes.—E. Wiedemann and G. C. Schmidt communicate the results of a lengthy investigation of potential gradients in vacuum tubes as influenced by the choice of a source of current, by heat, magnetism, ultra-violet light and photo-luminescence of the gas itself. They found that as soon as the same appearances were presented by a discharge from an influence machine, and that from a battery of accumulators, the potential gradients were equal to within 10 per cent. at all events. Even this difference may have been accompanied by differences of appearance, since the discharge of the influence machine was not steady. Hence, generally speaking, the luminous appearances are characteristic of the discharge potential. As regards methods of studying potential gradients, it is found that probes are unsuitable for discontinuous discharges and for discharges in narrow tubes. The discontinuity in the potential gradients in passing from wide to narrow parts of a tube explains the production of cathode rays at the points of transition. The potential gradient in the positive light column is largely independent of the width of the tube and the type of the discharge. This is somewhat analogous to the fact that in ordinary conductors the resistivity is independent of the dimensions and of the current intensity. Ultra-violet light and photo-luminescence are practically without effect upon the potential gradient. The heating effects in the glow light are quite out of proportion to the potential gradient there, probably owing to the fact that some rays are produced at the cathode and absorbed in the glow light. In the positive light, the whole of the energy given out by the discharge is converted into heat. A magnet brought near the positive column only increases the potential gradient indirectly by compressing the column.

[WIEDEMANN and SCHMIDT, *Wied. Ann.*, No. 10, 1898.]

Point Discharges with Oscillating Currents.—Experiments with Tesla apparatus have proved that rapidly alternating currents of high potential, when passing a pointed terminal, are capable of charging an insulated plate in the vicinity of the point positively, and not, as might have been expected, negatively. K. Wesendonck repeated the experiment with a Blondlot exciter with the same result. He now describes a very simple arrangement by which he is able to demonstrate and study the same phenomenon. One terminal of a Voss influence machine is put to earth, while the other leads to a spark gap, beyond which a fine needle is attached to the wire, which is also put to earth. Opposite the needle point is mounted a plate connected with an electroscope, the outer cover of which is put to earth. On working the machine the plate is always charged positively, whichever of the terminals of the influence machine is connected with the needle. On introducing a suitable self-induction, however, the plate is charged with the same charge as that of the terminal used. The difference between the two cases may be strikingly shown by introducing a closely wound coil of wire as a self-induction, and then pulling out the coil to a greater length, thus lessening its inductance. The author does not look for any explanation of this phenomenon to Pflüger's damping theory, but to a retardation which is greater for the negative than for the positive discharge.

[WESENDONCK, *Wied. Ann.*, No. 10, 1898.]

Polarised Electromagnetic Waves.—The observations made by Latrille (see *The Electrician*, Vol. LXI., p. 518), concerning the polarisation of electric waves by a metallic slit, had been previously made by K. Waitz, who did not, however, publish any account of them. The latter now proceeds to describe his own results in detail. They differ from those of Latrille in one important particular. In Latrille's experiments the transmitted energy always increased with the length of the slit, though not in proportion to that length. Waitz, on the other hand, found that the energy transmitted by the slit undergoes a periodic increase and diminution as the length of the slit is steadily enlarged. The minima are very pronounced, and closely approach zero. A maximum transmission occurs when the stationary wave at the slit has the same length as the resonator and electrometer combined. The first minimum occurs at a length of slit which is double that of the first maximum. The slit vibrates in two halves, and there is a node at the centre. When the resonator is displaced towards the ends of the slit, so as not to be at the node, the deflection of the electrometer increases.

[WAITZ, *Wied. Ann.*, No. 10, 1898.]

Low-Temperature Properties of Metals.—The anomalous behaviour of metals at very low temperatures is not confined to their resistivity. U. Behn has carried out some measurements of their specific heat, which have yielded interesting results. The method he adopted was that of mixtures, as being the handiest, and, on the whole, the most trustworthy. The metals dealt with were lead, platinum, iridium, palladium, copper, nickel, iron, and aluminium. The lowest temperatures were obtained by means of liquid air, and those between 0deg. and −80deg. by means of the usual mixture of solid carbonic acid and absolute alcohol. It was found that the lower the temperature the more was Dulong and Petit's law departed from. Between −80deg. and −180deg., the atomic heats, instead of ranging in the close neighbourhood of 6·3, varied from 6·0 (lead) to 4·0 (iron). The specific heats all diminished with decreasing temperature, and the more rapidly the higher their initial values. The author supposes that near the absolute zero they all have the same value, which is very small, and probably itself zero.

[BEHN, *Wied. Ann.*, No. 10, 1898.]

Digitized by Google

Temperature Coefficient of Dielectric Constants.—H. Pellat and P. Sacerdote have determined the dielectric constants of such substances as paraffin and ebonite at various temperatures. To ensure a uniform and known temperature in the specimens, which is a notoriously difficult task, they only made measurements at room temperatures, and varied the latter by suitable ventilation and other means. After keeping one such temperature constant for 24 hours it could be fairly assumed that the specimens had assumed the same temperature throughout their mass. The dielectric constant of paraffin diminishes as the temperature increases, at the rate of $3{\cdot}6 \times 10^{-4}$ per degree. The dielectric constant of ebonite, on the other hand, increases at the rate of $8{\cdot}8 \times 10^{-4}$ per degree. It follows that in charging a condenser at constant temperature the charge is not simply $\frac{1}{2}$ CV², but must be multiplied by a factor depending upon the temperature. If the dielectric is ebonite, the actual energy of the charged condenser exceeds by more than a quarter the value hitherto ascribed to it. If rapid the charges and discharges will be adiabatic, and variations of temperature are produced, amounting to about 0·001°C. These are two small to be placed in evidence.

[Pellat and Sacerdote, *Comptes Rendus*, October 17, 1898.]

Incandescent Safety Lamps.—To show that an incandescent filament is incapable of producing a gas explosion, H. Couriot and J. Meunier filled such a lamp with a 9·5 per cent. mixture of marsh gas and air, that mixture giving the greatest explosive power. The lamp was one of 10 c.p., and required 0·8 amperes and 45 volts. It was switched on and then filled with the explosive mixture. The effect observed was that the glow diminished rapidly, except at one point, and at that point the filament eventually broke. The fracture was only a fraction of a millimetre long, and the ends were pointed. No explosive effect was produced. Another lamp was then overfed with 53 volts. But the behaviour was the same, except that the life of the lamp was shortened to 20sec. No difference was observed in any other type of glow lamp. The explanation of this behaviour appears fairly simple. The marsh gas is gradually burnt up without explosion, and when the spark occurs at the rupture there is no longer an explosive mixture in the tube, but only water vapour and carbonic acid. The former collects in the bulb on cooling. In order to obtain an explosion, it is necessary to break the filament and produce a spark by shaking the broken ends till they collide. Even then the ends are sometimes welded together by the spark, and the lamp goes on glowing as if nothing had happened.

[Couriot and Meunier, *Comptes Rendus*, Oct. 17, 1898.

Addendum.—It appears that Wiedeburg's "New Electro-thermal Relation" between the emissivities and resistivities of metals (see these notes, Oct. 7, p. 772) was discovered by Lodge 22 years ago, and published in the *Phil. Mag.*, 1876, Vol. II., p. 524.

THE COMMERCIAL AND BUSINESS ASPECTS OF MUNICIPAL ELECTRICAL SUPPLY.

BY ALFRED H. GIBBINGS, M.I.E.E.

(*Continued from page 749, Vol. XLI.*)

Electric Motive Power (*continued*).

We have now dealt with the application of the electric motor to three important and useful purposes, viz., letterpress and lithographic printing, electric traction and cranes and hoists. Without specially considering the other applications given in Table VIII., it will suffice if we now enumerate, in the form of a summary, the general advantages of the electric motor. They are as follows :—

1. Speed practically constant under varying loads if required.
2. The cost in repairs is practically *nil* with a well-designed machine.
3. The smaller sizes may be fixed to a wall if necessary.
4. Occupies very small space, viz., about 4ft. square for any size up to 10 B.H.P.
5. Perfect silence in working, absence of smell and does not give off any gases.
6. Requires no attention, except oiling the bearings once or twice a week, and renewing the brushes occasionally.
7. Absolute freedom from vibration, thereby enabling the motor to be placed in any position in a building without expensive foundations.
8. The larger sizes can be readily adjusted to take up any slack in the belt, instead of cutting the belt and making a new joint.
9. A motor can be started and stopped by the simple operation of a switch. This arrangement obviates running the motor when not required, and, of course, effects considerable economy in the use of power.
10. As there is no reciprocating motion, the running is the steadiest that can possibly be obtained. The motors are therefore suitable for any kind of work.
11. Where a number of machines are used, and extensions are likely to be made, the use of additional motors is much cheaper and more adaptable to circumstances than extensions of shafting and counter-shafting. Odd and additional plant may be put down anywhere, doing away with the necessity of setting out with a line of shafting, and thus floor space can be utilised to greater advantage. The space above would also be free from open belts, cross-belts, pulleys, counter-shafting and other gearing. When these separately driven machines were not in use, there would be no long lengths of shafting being uselessly driven and wasting power.
12. Motors can be coupled direct to any class of machinery. They can be placed at any point where they will be least in the way, and in some cases an advantage may be derived from running two or three small machines from the one motor. For instance, bookbinders' stitching machines, of which a number are usually worked on one floor, might with advantage be coupled this way, as but small power is required, and not all being in operation at the same time, a single motor will be sufficient for the whole. Electric driving is the only system by which the *exact* power required to drive a machine can be accurately ascertained. Every other form of power, including steam engines, gas engines, oil engines and hydraulic engines, necessitates the use of a brake method in order to ascertain approximately the power required or developed. With electric power, and by means of an ammeter in the main circuit, the maximum and all variations of power is shown at a glance at any time, while the motor is actually working under its ordinary conditions.

Having dealt with the general advantages of electric motive power, we will now consider briefly the actual cost of working, instituting a comparison with the cost of gas, oil and steam. Hydraulic power may be omitted from the comparison, as the purposes to which it may be applied are very limited, the means of handling it and regulating it are very costly, and the repair and maintenance are serious items. In addition to these drawbacks, the service is liable to be affected by drought in summer and by frost in winter. It may, therefore, be dismissed as being by no means a competitor with electricity.

In order to make a fair comparison of the cost of power by steam, gas, oil and electricity respectively it must, first of all, be determined what we are to assume as the respective prices charged for these commodities. But there are other items which must also be taken into consideration, and these may be stated as follows :—

1. Horse-power of plant.
2. Average number of hours per annum during which the power is required.
3. Efficiency of plant.
4. The capital outlay of the complete plant.
5. The interest and depreciation on outlay.
6. Cost of repairs.
7. Rent, rates and taxes.
8. Wages for attendance.
9. Efficiency of gearing.

We will take these items seriatim, and assume the relative prices to be 12s. 6d. per ton for coal, 3s. per 1,000 cubic ft. for gas, 4d. per gallon for petroleum oil and 2d. per unit for electricity. In order to reduce these to a common basis for comparison, it is necessary to obtain the cost per brake horse-power per hour. In the best engines of each type respectively it has been found that 4lb. of coal for steam engines, 25 cubic ft. of gas for gas engines, 1½ pints of oil for oil engines and 830 watts for electric motors are each equivalent to one brake horse-power per hour. Hence in actual cost in pence per hour we get :—

Steam at 12s. 6d. per ton	0·26d.
Gas at 3s. per 1,000 cubic ft.	0·80d.
Oil at 4d. per gallon	0·75d.
Electricity at 2d. per 1,000 watt hours	1·66d.

These figures represent the brake horse-power (B.H.P.) on the pulleys of the engines and motors, and also (what is of equal and immense importance in making this comparison) they represent the result at the *full load* of the engine. With a *varying load* the efficiency of the engines rapidly decreases, while that of the electric motor remains practically the same, as will be shown further on.

Digitized by Google

The next two items to be considered are (1) the horse-power of the plant and (2) the average number of hours per annum during which the plant is required. It may be admitted that as steam plant is never put down for less than about 30 H.P., and hence that may be taken as a basis. The number of horse-power hours per day may be taken as 8, 6 and 4 respectively, although the first is very rarely reached. A steam engine may, for instance, be running for 9½ hours, but the load will be constantly varying from ¼ to possibly ¾ load, sometimes reaching full load for short periods. Hence the average must be taken, and, allowing 300 working days per year, we get 2,400 hours, 1,800 hours and 1,200 hours for 8, 6, and 4 hours per day respectively, or for 30 H.P., 72,000, 54,000 and 36,000 H.P. hours per annum respectively,

This brings us to the third point, viz., the efficiency of the plant at the average loads, which is found to be as follows:—

Table XI.

Plant.	Cost of fuel per brake horse-power per hour on varying loads. Horse-power hours per annum.		
	72,000	54,000	36,000
Steam	0·26d.	0·34d.	0·46d.
Gas	0·80d.	1·00d.	1·20d.
Oil	0·75d.	0·94d.	1·12d.
Electric	1·66d.	1·66d.	1·66d.

The next items for consideration have a much more important bearing on the actual and comparative costs of running. They consist of (1) capital outlay, (2) interest and depreciation, (3) repairs and maintenance, (4) rent, rates and taxes and (5) attendance. For a 30 H.P. plant these may be estimated as follows:—

Table XII.

Items.	Cost per annum.			
	Steam.	Gas.	Oil.	Electricity.
Capital	£500	£250	£250	£300
Interest and depreciation, 10%	£50 0	£25 0	£25 0	£30
Repairs, 5%	25 0	12 10	12 10	(2½%) £7 10
Rent, &c., for space occupied...	10 0	5 0	5 0	Nil.
Attendance	100 0	50 0	50 0	Nil.
Total	£185 0	£92 10	£92 10	£37 10
Cost per B.H.P. per hour for 72,000 hours ..... =	0·61d.	0·30d.	0·30d.	0·13d.
Ditto for 54,000 hours... =	0·82d.	0·41d.	0·41d.	0·17d.
Ditto for 36,000 hours... =	1·22d.	0·61d.	0·61d.	0·26d.

Table XII., together with Table XI., provides us with the necessary data wherewith to ascertain the actual cost of a brake horse-power hour for the respective plants under similar conditions, but with varying loads. These combined results are given in Table XIII.:—

Table XIII.—*Average Cost per Brake Horse-Power Hour in Pence for Varying Annual Loads.*

Plant.		72,000 hours. Per hour.	54,000 hours. Per hour.	36,000 hours. Per hour.
Steam	Running costs...	0·26d.	0·34d.	0·46d.
	Capital costs ...	0·61d.	0·82d.	1·22d.
	Total	**0·87d.**	**1·16d.**	**1·68d.**
Gas	Running costs...	0·80d.	1·00d.	1·20d.

Electricity ...	Running costs...	1·66d.	1·66d.	1·66d.
	Capital costs ...	0·13d.	0·17d.	0·26d.
	Total	**1·79d.**	**1·83d.**	**1·92d.**

It will be seen that these figures as they stand in the table are not favourable to electricity as a motive power. This is due to two reasons. First, the comparison between the respective motors is that of brake horse-power, taken at the shaft of each machine; and secondly, the price for electricity for power purposes, viz., 2d. per unit, is high.

To take the first of the above causes, it must be admitted that in comparing the costs of running at the point where the power is delivered by each engine, viz., at the pulley of the crank or armature shaft, the electric motor is not much cheaper, and in this instance is dearer, than the other three. It is clear, however, that in actual practice that point is not where the comparison is either useful or needed. The point at which the comparison should be made is the point of application of the power to the machinery or object to be operated or driven. Unless the gas, oil or steam engine is to drive one machine only, the necessity arises in the case of these engines to use intermediate gearing in the forms of shafting, belting, ropes, spur wheels, bevel wheels, &c. This gearing forms a very much greater proportion of the power required *per machine* than would appear to be the case. It may be taken as varying from 25 per cent. to 100 per cent. above the actual power of the machines when all are in operation. It is no uncommon occurrence, however, for only a small proportion of the machines to be at work while the engine is driving the whole of the shafting. Electric motors, of course, do away with nearly all this complication and waste, because they can be coupled direct to each separate machine, and in addition are not required to run when the machine is not in use. We can go even further than this, and start and stop the motor in a moment as the work on the machine is varied. As regards steam, gas and oil, therefore, it will be necessary to at least double the figures given in Table XIV. before accepting them as representing the actual working cost.

There is also another important feature in connection with the economy of electric motors. I refer to the efficiency at varying loads. It may be taken for granted that no single piece of machinery maintains a full load for any considerable length of time, and hence the efficiency of the driving engine at quarter, half and three-quarter load, &c., becomes important. The efficiency of the electric motor is much higher at all loads than either steam, gas or oil engines. The cost, therefore, of running an electric motor will be represented by the actual resultant taken on the average of the varying loads. This feature is illustrated in the accompanying curve (Fig. 5), which has been taken from the most modern machines. It will be seen that the maximum horse-power was 6·4 and the duration of time 18min., which, if the maximum power had been a constant load, would represent two horse-power hours. But after the resultant has been carefully obtained with a planimeter, the actual horse-power hours are found to be 1·06. This difference between the maximum horse-power required and the mean horse-power used is rarely taken into account or even understood by many small power users. It is a most difficult thing to get them to appreciate.

The second reason of the unfavourable comparison of cost per brake horse-power hour for electric power, as given in Table XIII., and to which brief reference has already been made, is that the price of 2d. per unit is high. It will be shown later on in this section that electricity for power purposes can be supplied at 1d. per unit from a central electric lighting station, and that a considerable profit can be made at that price. There are very few instances in which any private steam or gas plant can compete with electricity at 1d. per unit. In some towns, however, the charge for electricity for motive power is as high as 3d. per unit. The figures in Table XIV. give the cost per brake or electrical horse-power per hour for varying prices per Board of Trade unit. This table should be referred to only in conjunction with Fig. 5 and the explanation thereto.

The Effect upon the Output and Costs of the Generating Station.—There is very little necessity to enlarge upon the beneficial effects from a financial point of view upon the works costs of the generating station of a good day load in the form of a demand for electric motive power. The reader is referred

to the section on "How to Charge for Electrical Energy," pp. 8, 76 and 179, Vol. XLI. It can be readily understood that in many cases electric motors may be required for a very short time per day: such cases, for instance, as coffee-grinding, hair brushing, restaurant lifts, &c. It is found in practice, however, that the rate of charge which has to be made for electricity for lighting purposes, may be considerably modified in regard to motive power. This arises, of course, from the fact that electric motors are in use principally, and to a great extent, in the daytime, whereas the demand for the electric light forms the well-known "peak" at the time of dusk, when the sum of all the demands is simultaneous. It is often stated that during the winter months the respective sums of the demands for both lighting and power are also simultaneous, thereby necessitating the same initial charge per unit for the first hour's average daily demand in both cases. As a matter of experience and observation it is found that such is not the case entirely. A certain proportion of the power for motors is bound to overlap the maximum of the lighting load, but the greater proportion undoubtedly occurs before 5 p.m. throughout the year.

In Bradford the maximum charge for motive power is 2½d. per unit with the sliding scale, as in Table XV., reducing the price according to the average daily use. The calculations are based upon a working year of 300 days. Wright's Demand Indicator is used to ascertain the maximum horse-power, which serves the double purpose of also showing whether the consumer's motor has been applied to work beyond the capacity for which it was designed.

The charges for electricity for power purposes will be 2½d. per unit, for an average use for four hours and under per day of the maximum power actually required. If the power is used for an average of over four hours per day, the charge will be reduced in accordance with the scale on the next page.

From the statement given therein any number of units may be ascertained by taking the amperes that are multiples of 100, say, 125, thus :—

Over	Under						
97½ ...	100=30·83 ...	11,000 ...	13,000 ...	15,500 ...	19,000 ...	24,000
22½ ...	25= 7·70 ...	2,750 ...	3,250 ...	3,875 ...	4,750 ...	6,000
120 ...	125=38·53 ...	13,750 ..	16,250 ...	19,375 ...	23,750 ...	30,000

and so on.

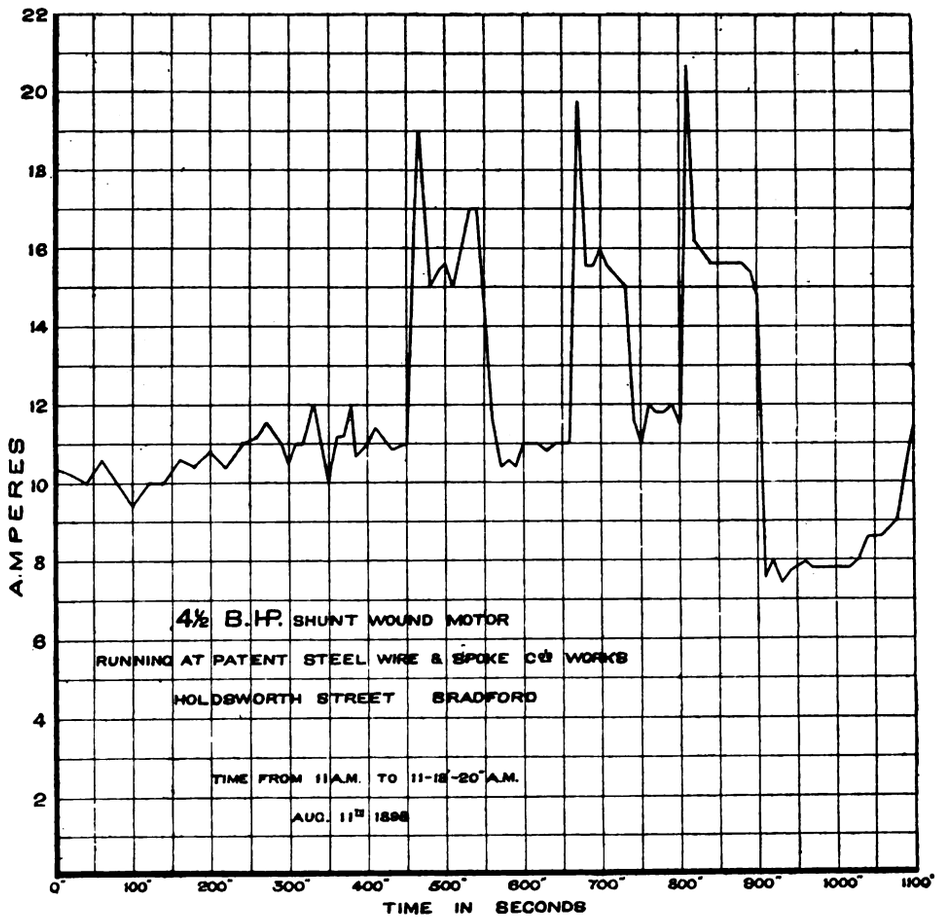

Fig. 5.

In addition to, and consequent upon the effect which the demand for motive power has upon the output and generating costs of the electricity works, there are sundry advantages from a generating point of view which have not yet been taken into consideration. There is less necessity for "banking" boiler fires, as the boilers are in more general use. This reduces the quantity of coal per unit sold, and in one municipal electricity works the saving effected in three years was ¼d. per unit, the cost being reduced from ½d. to ¼d. The radiation losses due to keeping steam pipes warm all day will remain practically the same, but per unit sold will, of course, be less with a day load than without. Another important effect occurs with the more continual running of the engines. The extra wear and tear will be neglible, indeed an advantage will accrue from their more frequent use. With an electric lighting load only, the greater portion of central station machinery is standing idle for long periods during the summer months, which, from an engineering point of view, is even more dele-

97½	100	30·83	11,000	13,000	15,500	19,000	24,000

terious than continual running. Standing machinery has a tendency to become rusty, and in order to avoid this each set has to be run for a few hours weekly with no load. The same applies to the generators, damp and dust doing greater harm than when they are frequently in use.

(*To be continued.*)

MR. W. H. PREECE'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF CIVIL ENGINEERS.*

(*Concluded from page 51.*)

Lighthouses.

The introduction of electricity into our lighthouses has not been such an unqualified success as into our ships. No new electric light has been installed on the coast of Great Britain since St. Catherine's (Isle of Wight) was fitted up in 1888. Other electric lamps are to be found at the South Forland, at the Lizard, and at Soutar Point; only four lighthouses in all upon our coasts. This is due chiefly to the great prime cost of its installation and to the annual expense of its maintenance. But the sailor himself is not enamoured of it. It does not assist him in judging distances. It is too brilliant in clear weather, while in bad weather it penetrates a fog no further than an ordinary oil lamp. Moreover, great modern improvements have rapidly followed each other in other apparatus, lenses and lamps. A third order light of to-day can be made superior to a first order light of ten years ago. Oils have improved, and gas has been introduced. Lord Kelvin proposed that lighthouses should signal their individuality to passing ships by flashing their number in the Morse alphabet. But the Morse alphabet, in 1875, was as unknown as Egyptian hieroglyphics to our nautical authorities. The same end was obtained with less mental exertion by occulting and group-flashing systems. A new and very promising plan has recently been introduced in France, called the "Feux-éclairs" or "lightning flash" system. It has been installed in many places, but especially at the two Capes dominating the Bay of Biscay. Nothing more brilliant or more effective is to be seen anywhere than the lights that rapidly sweep across the horizon, like well-directed flashes of summer lightning, with a motion that conveys the idea of a wave of some illuminated spirit-arm warning the navigator away from the rocky dangers of Ushant. Our Trinity House has not yet introduced this plan. Any change of our well-considered and deeply-important coast-lighting system is not to be hastily effected. We are very proud of our well-guarded shores. Every headland and landfall, every isolated rock, all dangerous shoals and banks and narrow channels in lines of trade are so illuminated that navigation by night is as safe and easy as by day. Lighthouses and lightships stud our channels. Most of them are placed in direct communication with our Post Office telegraph system, so that the speediest help can be secured in moments of difficulty and danger. We, however, want improvement in fogs and storms. Here electricity steps in. I wrote, in 1893, of wireless telegraphy:—"These waves are transmitted by the ether; they are independent of day or night, of fog or snow or rain, and, therefore, if by any means a lighthouse can flash its indicating signals by electromagnetic disturbances through space, ships could find out their position in spite of darkness and of weather. Fog would lose one of its terrors, and electricity become a great life-saving agency." We are nearing that goal.

Traction.

Electrically worked railways originated in Europe. The first experimental line was constructed by Dr. Werner Siemens, in Berlin, in 1879. When I visited America in 1884 there was only one experimental line at work in Cleveland, Ohio. Now there are more miles of line so worked in Cleveland alone than in the whole of the United Kingdom. The reason for this is not difficult to comprehend. The climatic influences of the States, the habits of the people, the cost of horseflesh, the necessity for more rapid transit, soon proved the vast superiority of electric over every other form of traction. Horses and cables will soon disappear. In England the Tramways Act of 1870 has been restrictive. It deferred the real solution of the question for 21 years. Its avowed tendency has been to throw the industry into the hands of the municipalities. Private enterprise has, therefore, not been encouraged, and municipalities have not taken it up. Local authorities have now been educated. The successful progress in the States and on the Continent has proved contagious, and everywhere our great cities are rising to the occasion. Indeed, to neglect to supply tramways where they would be useful, healthful and valuable is, to a certain extent, an abuse of the trust confided to the municipality by the Legislature. Rapid and convenient suburban transit is a social factor of great importance to the working classes, who can be readily transported from close quarters to pure air and healthy dwellings. Hamburg is one of the best trammed cities on the Continent. The trams were constructed by private enterprise under lease from the municipality. The latter supplies the electric energy. The tramway company is bound to take the current at a fair and reasonable price; but they have also to pay a tax on the gross receipts, which is set aside by the local authority as a sinking fund, so that on the expiry of the agreement the town will have the capital to purchase the tramways. Corporations in this country who have secured a provisional order for the installation of electric light have secured also legal powers to supply electric energy for all purposes. It is, therefore, their right, and it may become a very valuable property. The duplication and multiplication of central electrical stations is likely to become a serious evil. It is absurd to see two buildings erected where one only is needed, and two causes of nuisance perpetuated where none need exist. I have already pointed out the economy of combining electric lighting and tramway working. The relative merits of overhead and underground conductors, and the use of storage batteries, are practically the only important engineering questions under discussion. The underground conduit system has been materially helped by the practical object lesson to be seen in New York, where the tramways are being very successfully worked on this plan. The trolley system is much more economical. Its erection does not interfere with the traffic of the streets. The principal objection to it is its anti-æsthetic appearance, but it is wonderful how ideas of utility and the influence of custom make us submit to disfigurement. What is more inartistic than a lamp-post, or more hideous than the barn-like appearance of many a railway terminus?

The corrosion of water and gas pipes, the disturbances of telegraphs and magnetic observations, are serious questions arising from the introduction of powerful currents into the earth; but, fortunately, the remedies are simple, easily obtainable, and very effective.

I have alluded to the proposed working of our underground railways. The success of the Mersey Dock line and of the South London and Waterloo lines have placed the question beyond controversy. The problem to be solved is, How is the conversion from steam to electricity to be effected without interfering in any

way with the existing traffic or with the existing permanent way? This is not to be solved on paper. It must be determined by actual trial, and this is about to be done on the short line connecting Earl's Court and High-street, Kensington. Electric traction as an economical measure in all cases of dense traffic is so certain that every great railway company must consider, sooner or later, the working of their suburban traffic by electricity. This experiment on the Metropolitan Underground Railways, therefore, should interest them all. It is a question deeply affecting the interests and comfort of the public and the condition of the congested traffic of our streets.

The storage battery fulfils a very important function in the economical working of an electric railway. It equalises the pressure on the circuits. It meets the fluctuations of the load. It takes in current when the load is light; it lets out current when the load is heavy. It thus secures the continuous working of the engines at their full constant and most economical conditions, and it enables the engines to be shut down altogether when the load is very light as it is at night, in the early morning, and on Sundays. In Buffalo, the battery is charged by energy from Niagara, 21 miles away, and the local engines are shut down for 12 hours every day, and for 10 hours on Sunday. Electric traction is invading even our streets. When the real storage battery is produced, the automobile problem will be solved. At present, steam and oil are active competitors.

The Transmission of Power.

The energy wasted in waterfalls is enough to maintain in operation the industries of the whole world. Great cities as a rule are not located near great falls; nor has a beneficent Providence provided great cities with waterfalls, as, according to the American humourist, He has with broad rivers. There is but one Niagara, and we are seeing how industries are rather going to the falls than the energy of the falls is being transmitted to the industrial centres. The arbitrament of money is limiting the distance to which energy can be profitably transmitted. The cataracts of the Nile can be utilised in irrigating the waste lands of the upper regions of the river, but their energy cannot compete, at Alexandria, with that of coal transported in mass from England.

In mines electricity is invaluable. It is used for moving trams and for working hoists. It lights up and ventilates the galleries, and by pumping keeps them free of water. It operates the drills, picks, stamps, crushers, compressors, and all kinds of machinery. The modern type of induction motor, having neither brushes nor sliding contacts, is free from sparks and safe from dust. Electrical energy is clean, safe, convenient, cheap, and it produces neither refuse nor side products. It is transmitted to considerable distances. In mountainous countries the economical distance is limited by the voltage which insulation can resist; 40,000 volts are being practically used between Provo Canyon and Mercur, in Utah, in transmitting 2,000 H.P. 32 miles.

The above table records some interesting installations.

Conclusion.

I have touched lightly—I fear too lightly—upon some of the applications of electricity. I have confined myself, in a very general sense, to those with which I have been personally associated. I have shown how electricity began its beneficent career by protecting our lives and property from the disastrous effects of Nature's dread artillery, how it facilitates intercommunication between mind and mind by economising time and annihilating space. It

> "Speeds the soft intercourse from soul to soul,
> And wafts a sigh from Indus to the Pole."

By its metallic nerves it brings into one fold not only the scattered families of one nation, but all countries and all languages, to the manifest promotion of peace and general goodwill. Not only does it show us how to utilise the waste energies of Nature, but it enables us to direct them to the place where they are most wanted, and to use them with the greatest economy. It opens to our view Nature's secret storehouses, presenting us with new elements, new facts and new treasures. It economises labour and purifies material. It lightens our darkness in more senses than one, and by enabling us to see the unseen, it tends to aid the gentle healing art and to alleviate both suffering and pain. It aids us in the pursuit of truth, and it has exploded the doctrine that the pursuit of truth means the destruction of faith. I have occupied your time sufficiently I hope to impress upon you the universality of electricity. Its flood gates were opened when our good Queen ascended the throne, and during her glorious reign it has overflown all the fields cultivated by the engineer. Though its followers are now regarded as specialists, the period is not distant when it must cease to be a speciality. Its facts and tenets, its science and practice, must form the framework of the profession of the engineer. Every engineer must ultimately become an electrician; and electricity will be the most general, the most useful, and the most interesting form in which he applies the fundamental principles of energy to the wants, the comforts and the happiness of mankind.

TESTIMONIAL TO RICHARD COLLETT.

On Friday evening last, at the Trocadero Restaurant, London, took place one of those functions which mark most acutely the passage of time, and call attention to the gradual retirement from active service, one by one, of the early workers in electrical enterprise. Were it not for the severance of the old ties, such gatherings as that of Friday would leave nothing but pleasant memories, for it is undoubtedly the case that, at these "meetings for farewell," the pioneers of practical telegraph work are prone to give those intensely personal particulars of the trials and troubles of their early work, which at no other time can they be induced to dilate upon. The present occasion was no exception, and we heard from Mr. H. A. C. Saunders unrecorded incidents of Atlantic cable campaigns.

Mr. J. Denison Pender occupied the chair, and, in addition to Mr. Richard Collett, the company included Messrs. W. H. Axworthy, C. B. Barnes, W. Barnett, G. R. Birch, R. T. Brown, T. A. Bullock, W. H. Burman, S. Collett, F. Dawes, W. Dover, Geo. Draper, Ch. Gerhardi, W. P. Granville, Capt. Greey, F. E. Hesse, W. Hibberdine, E. Steer Hodson, W. W. Howell, G. C. Jack, J. Jack, W. Judd, F. Lucas, J. F. Mills, O. Moll, Dr. Muirhead, G. R. Neilson, F. C. C. Nielsen, Capt. Perkins, H. C. Plank, H. E. Popplewell, J. Rippon, H. A. C. Saunders, H. St. L. Smith, W. O. Smith, W. S. Smith, Geo. Tucker and Dr. T. Wholey.

After an excellent dinner, and a cordial reception of the usual loyal toasts,

The CHAIRMAN, in presenting the testimonial and proposing Mr. Collett's health, referred in kindly terms to the excellent services rendered by Mr. Collett to telegraphs. After briefly reviewing Mr. Collett's career in the Atlantic telegraph service, from 1857 to 1870, and to the fact that he was traffic manager of the first Atlantic cables opened to the public, he dwelt upon his association with the Brazilian Submarine Company, and pointed to the remarkable success which that Company had from the first attained having paid a 6 per cent. dividend from the commencement. This success was not, however, immediately reflected in the Stock Exchange, for the Company's shares were at a very low figure. But that was not for many years, and the £10 shares now stood about £16. He referred to the singularly few repairs which the Company's cables had required, and to the fact that from the first the policy of the Directors had been to have no property in cable ships. That might be termed a policy of pluck and ability, for it had proved a success, and had shown the wisdom and foresight with which the Brazilian Submarine Company had from the first been conducted. No small share of this success was due to the work of their guest, whose popularity in the service was shown by the fact that his friends in all parts of the world had contributed to the handsome and useful testimonial which they were able to present to Mr. Collett as a small evidence of their regard for him as a friend and associate. Mr. Collett had requested some time ago that he should be permitted to retire, but important negotiations were then in progress, and it was felt by the Directors that Mr. Collett should remain in active work until these negotiations had culminated in success. That period had now been reached, and

Digitized by Google

the Directors felt that they could no longer withhold their consent to Mr. Collett's wish to retire while in full health and strength. He (the Chairman) and all who knew Mr. Collett intimately sincerely hoped that this period of well-earned repose would be a long and pleasant one. It was a wrench to their feelings to part in business with an old friend, but they looked forward to his friendship in the future as in the past.

The toast was drunk with musical honours.

Mr. RICHARD COLLETT, who was much affected by the enthusiasm with which the toast was received, spoke very feelingly of the uniform kindness and consideration he had always received from the Directors and his colleagues. He thanked everybody for this kindness and consideration, and he asked that his appreciation of the handsome and useful testimonial which they had been good enough to present to him might be conveyed to all the donors. Such a gathering for such a purpose as the present was a reward for a long and active career, and answered conclusively the query, "Is life worth living?"

Mr. H. A. C. SAUNDERS proposed the health of the Chairman, and associated with his remarks the subject of Submarine Telegraphy. He said those present knew their Chairman's intimate connection with the development of telegraph work, and how he had succeeded his father, the late Sir John Pender, who entered telegraphs as far back as 1854 as Director of the Magnetic Company, in the days of Whitehouse and Brett. At that period the length of submarine cable laid in all parts of the world was only 735 miles. He referred to his own early connection with telegraphic work, when associated with Whitehouse and Brett in carrying out experiments. It was, he said, remarkable how very early in the history of submarine telegraphs the American nation had shown an eagerness for rapid communication with the United Kingdom. The demand for news was so great that when the mail ships arrived at Cape Race, boats came out to meet them, and papers containing news were thrown into the water and were taken ashore by these boats. In order to obtain command of the lines when news was expected bogus messages were manufactured, so that uninterrupted possession of the lines might be secured. Meantime "subaqueous" and submarine lines were being laid in Europe, and experiments were being conducted in order to extract from these cables their utmost capacity in speed and accuracy. The longest deep sea cable in those days and up to 1856 was 110 miles of line laid in 500 fathoms of water. In 1856, when he joined the Atlantic Company, they had but limited knowledge and experience, and it was nothing short of audacity to make and attempt to lay an Atlantic cable with the extremely limited knowledge at command; it was, therefore, not surprising that, on October 20, 1858, that cable failed. In May, 1858, he commenced what proved to be a 15 months' expedition to Newfoundland, and returned to London in August, 1859, and again in the next month left Galway with a man whose name should not be left unrecorded in the annals of submarine cable work—Captain Kell, a retired mercantile marine man—with whom he arrived at St. John's, Newfoundland, after a nine days' passage. They then chartered a fishing boat, the "Hibernia," and he might mention that very remarkable craft were, in the early days of the expedition, drafted into the service. In October of the same year they encountered a great storm in Bull's Arm Bay, which badly damaged their boats, and played havoc with their electrical outfit, which, by the way, he would mention cost about £25. It was found by Nov. 5th that the weather was too bad to continue operations, and so they returned to England. In 1860 a more important expedition to recover the lost cable was organised, and a Deal lugger, the "Industry," was, on Capt. Kell's advice, engaged, and on April 28th of that year, his friend Richard Collett and he left Galway for Newfoundland, where they arrived in seven days. Very rough weather was subsequently encountered, and it was not until June that they were able to make a start. On June 12th they began to recover the lost cable, but the weather was so bad that their movements were greatly impeded. On June 26, 1860, Cromwell Varley joined them in a tug. However, on July 3rd of that year they abandoned the work and returned to England, and on the 27th of August terminated Richard Collett's and his own then engagement with the Atlantic Company. They were, however, together again in Messrs. Glass, Elliott and Co.'s service, and in the laying of the Malta-Alexandria cables. They drifted apart for some years after this, Mr. Collett joining the Anglo-American Company and he (the speaker) being at Malta. However, they were ultimately together again with the Eastern and associated companies, Mr. Collett having joined the Brazilian Submarine Co. on its establishment, and he taking service with what subsequently became the Eastern Telegraph Co. In all this great telegraph enterprise the late Sir John Pender had taken an active part, and his son, their chairman this evening, had followed and was following his father in this great national work. He had great pleasure in proposing the toast of their Chairman.

The toast was drunk with enthusiasm.

The CHAIRMAN, in reply, referred to his own long connection with telegraphs, and said that he looked upon his duties in the telegraph service as a trust handed him by his father. There was present that evening the representative of a company which had done a great pioneer work in connection with telegraphs—Mr. F. C. C. Nielsen, of the Great Northern Company. He could not refrain from associating with the name of his father that of the late Sir James Anderson, nor must they omit, in a gathering like this, to give due credit to the manufacturers of submarine cables and to the inventors and makers of the delicate instruments which were necessary in submarine cable work. They had a representative there that evening of the Telegraph Construction and Maintenance Co., and Dr. Muirhead was also present. With regard to the telegraph companies, there were at one time, no doubt, serious jealousies, but these had been and were being overcome, and they now represented a bond of strength and good feeling. For himself, what success he had achieved he attributed largely to the valuable assistance rendered by the staffs of the companies with which he was associated.

This concluded the toast list and the proceedings, which had been throughout of an enthusiastic nature, terminated.

The testimonial to Mr. Richard Collett consisted of a pair of handsome candelabra, a three-bottled spirit frame with cable design, a case of fish eaters and a pair of fish servers, a case of nut cracks, a double inkstand, and a salver, all of silver, designed and manufactured by Messrs. Mappin and Webb.

CORRESPONDENCE.

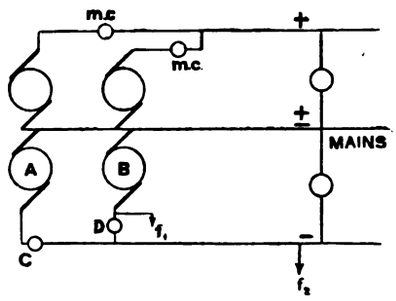
THE BREAKDOWN AT BRIGHTON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having followed closely the Notes, in the two last issues of *The Electrician* regarding the breakdown at Brighton, perhaps the following account of a similar occurrence may be interesting to your readers, and help to explain the cause of the minimum cut-outs opening.

About eight years ago (in the United States), whilst in charge of a large station, there were four 150 kilowatt machines running in two sets of two in parallel on the three-wire mains.

Each dynamo (in addition to other apparatus) was provided with a minimum cut-out. The four machines were nearly loaded, when suddenly the minimum cut-out D acted, the cause being due to a fault developing on the machine B, when a band came loose: a fault f_2 on the main short-circuited the cut-out f_1 to f_2, and the apparatus opened.



The machine A was now overloaded, the dynamo B running as a motor; then the field of A dropped, owing to the engine slowing down, and its minimum cut-out *c* also worked. An extinction of the lights on this side of the three-wire system then took place. The machines were self-excited, but later on were separately excited. The fault f_2 in the meantime, it should be added, had been completely burnt off, and it was afterwards found to have been caused by a subsidence of the pavement at a certain place.

A wholly different type of minimum cut-out was afterwards used with every success of a design that I have never seen employed in Europe, and which I feel sure would have prevented the trouble at Brighton.—Yours, &c.,

London, Nov. 6, 1898. J. D. DALLAS.

LEGAL INTELLIGENCE.

Kaye v. Croydon Tramways Co. and Others.

In the Chancery Division on Wednesday, before Mr. Justice Kekewich, Major-General G. F. Kaye brought an action, on behalf of himself and the other members of the Croydon Tramways Co., against the company, its directors, and the British Electric Traction Co. (Limited), for a declaration that an agreement dated Nov. 25, 1897, between the tramways company and the traction company for the sale to the latter company of the tramways company's undertaking, and a resolution approving the same purporting to have been passed at a meeting of the shareholders of the tramways company held on Dec. 14, 1897, in pursuance of a notice dated Nov. 26, 1897, were *ultra vires* and ought to be set aside, and for an injunction to restrain the defendants from carrying out the agreement, and also claiming relief against the Directors of the tramways company personally. This matter has been before the Courts previously, and now came on for trial.

Mr. Justice KEKEWICH said it was agreed that plaintiff must have an order for payment of his costs, so far as the action turned upon the question of insufficient notice to the shareholders of the date of meeting to consider the agreement. But the whole case of the plaintiff depended on the charge of fraud. Of course, if in the circumstances of the case fraud had been made out, it would have been a very grievous charge. The plaintiff had not based his case on negligence, saying that the Directors had too easily sanctioned this agreement, and had not brought in expert evidence, but he had put it distinctly on the ground of fraud. If fraud was charged it ought to be proved ; if it was not proved the usual consequences must follow. To his lordship's mind it had not been proved. He dismissed the action, so far as it alleged fraud, and made an order giving the defendants (the British Electric Traction Co.) the costs of the action and the defendants (the Directors) the costs of the action so far as they did not relate to the insufficiency of the notice and the invalidity of the resolution.

Boyce, French and Bulwer v. The Alexandra Palace Electric Railway Co.

At Wood Green (London) County Court, Judge Edge heard three actions for damages for personal injuries arising out of an accident on the electric railway established in the grounds of Alexandra Palace. The accident occurred on Whit Monday last, and a number of passengers were injured. Council explained that the railway car was descending the slope from the Palace to Wood Green when the car ran away at a great speed and collided with another car standing at the end of the track. The plaintiff Boyce claimed £20. 5s. and French £10, and judgment was given for these amounts with costs. Bulwer claimed £20 and obtained £10 and costs. The defendants in the action did not appear.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free ; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net ; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition ready in November.*

"Practical Notes for Electrical Students."—By Messrs. A. E Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s , post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free ; abroad, 11s.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net ; in sets of any three, 1s. net ; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net ; or in handy portfolio, price 12s. net ; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Wireless Telegraphy : Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d. ; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons." — A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d. ; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97.' A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free ; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free ; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour ; price 7s. 6d. ; by post, 7s. 9d. ; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d. ; post free, 13s. ; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free ; cloth 2s. 9d. Single Primers, 3d. each, post free.

"Electromagnetic Theory."—By Oliver Heaviside. Vol. I., price 12s. 6d. ; post free, 13s. *Nearly ready.*

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth also ready. Price 7s. 6d. ; abroad, 8s. Prospectus on application.

"The Potentiometer and its Adjuncts" : A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s , post free ; abroad, 6s. 6d. Digest post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"Armature Windings of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"The Manufacture of Carbons for all Electrical Purposes."—By Francis Jehl.

"Electromagnetic Theory." By Oliver Heaviside. Vol. II.

"Secondary Batteries, their Design and Manufacture."—By E. J. Wade.

"Primary Batteries : Their Construction and Use."—By W. R. Cooper.

"Practical Telephony."—By Dane Sinclair and F. C. Raphael.

"'The Electrician' Wireman's Pocket-book."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The Electric Lighting committee of the *Salford* Corporation invite tenders for the supply and erection of the following : (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another

Digitized by Google

column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walness-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, by Dec. 1.

As will be seen from our advertisement pages, the *Glasgow* Corporation invite tenders for providing and erecting switchboards and instruments at the new electricity works, Port Dundas. Copies of the specification, &c., may be had from Mr. W. A. Chamen, city electrical engineer, 75, Waterloo-street, Glasgow, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, not later than Monday, Dec. 5.

The *Glasgow* Corporation also invite tenders for the supply of about 800ft. of cast-iron pipes (21in. diameter) and certain cast-iron pipes (22in. and 29in. diameter), with special castings, for the Port Dundas electricity works. Tenders to town clerk, by 22nd inst.

The Corporation of *Blackpool* invite tenders for trolleys, trolley wire and other material in connection with the conversion of their present conduit system to the overhead system. Specifications may be obtained from the Borough electrical engineer, Mr. Robert C. Quin, and tenders are to be sent in not later than Tuesday, Nov. 22. Further particulare are given in our advertisement columns.

The *Dublin* United Tramways Co. invite tenders for the supply of general stores, including electrical supplies, car fittings, ironmongery, &c., for the year 1899. Tenders to the chairman of the Company, 9, Upper Sackville-street, Dublin, by the 5th prox. For some further particulars see advertisement on another page.

The Electric Lighting committee of the borough of *Middlesbro'* require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers and accessories, mechanical stokers, feed pumps, injector, economiser and electric motor; (*b*) slow speed steam dynamos and accessories; (*c*) condensing plant and pipe work; (*d*) overhead travelling crane; (*e*) switchboard and instruments; (*f*) accumulators; (*g*) trenching, cables, &c.; (*h*) meters. Tenders to Mr. Geo. Bainbridge, Municipal Buildings, Middlesbro', by Nov. 29.

The *Great Northern Railway Co.* (*Ireland*) invite tenders for (1) Lancashire boilers; (2) engines, dynamos, pumps, steam and exhaust pipes, &c., cranes, feedheaters and tools; (3) switchboards. Tenders to the Company, Amiens-street Terminus, Dublin, by 19th inst.

The *British Electric Traction Co.* require tenders for the supply of about 12,000 tons of granite setts required during the ensuing twelve months. Particulars from the company's permanent-way engineer, Donington House, Norfolk-street, Strand, London, W.C.

The Electric committee of the *Belfast* Corporation require tenders for the supply and erection of four 400-kilowatt steam dynamos. Specification, &c., from the city electrical engineer (Mr. Victor A. H. McCowen). Tenders to Sir Samuel Black, town clerk, Belfast, by noon of 17th inst.

The *Belfast* Harbour Commissioners require tenders for the supply of nine iron latticed-built electric light masts, 70ft. high from the ground lines with suitable base. Tenders to Mr. W. A. Currie, Harbour Office, Belfast, by Nov. 14.

The Corporation of *Barrow-in-Furness* invite tenders for the supply and erection of cast-iron lamp columns, arc and incandescent lamps, automatic switches and fittings. Tenders to Mr. C. F. Preston, Municipal Offices, Barrow-in-Furness, by noon of Nov. 14.

The *Edinburgh* Corporation invite tenders for the following plant for their electric lighting station in McDonald-road:—(1) Marine type boilers and mechanical stokers, (2) engines and dynamos. The engines must be of the Willans or Belliss type. Tenders to the offices of the town clerk (Mr. Thomas Hunter), Town Hall, Edinburgh, by Nov. 14.

The *Leatherhead* District Council invite offers from persons willing to take over their Electric Lighting Order (1898). Offers to Council Offices, Leatherhead, by Nov. 21.

Tenders are invited for the supply and fixing of two engines and dynamos at the *Southampton* County Lunatic Asylum, Knowle, near Fareham. Tenders to Mr. John R. Wyatt, Knowle, by Nov. 16.

The *East Indian Railway Co.*, Nicholas-lane, London, E.C., invite proposals for the supply of 18 instruments for nine blocks (for single line); 80 instruments for 41 stations (for double line), and six spare instruments. Tenders to secretary by 1 p.m. Nov. 23.

The *Midland Railway Co.* require tenders for stores, including telegraph instruments, stay rods and bolts, telegraph and signal wire, &c. Tenders to secretary, Derby, by 9 a.m., 15th inst.

The *Irish Board of Public Works* invite tenders for the hire of plant required for the electric lighting of the State apartments, Dublin Castle, during the next Castle season. Tenders to the secretary, by 10 a.m., 14th inst.

The horse tramways of *Rheims* are about to be converted to the electric trolley system. Proposals from firms prepared to contract for the equipment of the lines should be forwarded to La Compagnie de Tramways de Rheims, Sharbeeck, Brussels.

The *Shanghai* Municipal Council invite tenders for the construction and working of about 23 miles of electric tramways on the trolley system. Plans, &c., from Messrs. John Pook and Co., 8, Jeffreys-square, St. Mary Axe, E.C. Further particulars from Mr. Charles Mayne, whose cable address is "Dynamo Shanghai." Tenders to secretary by noon of March 15 next.

The Consul-General of the *South African Republic*, Nicholaas Witsenkade 9, Amsterdam, invites tenders for the supply of iron telegraph poles. Tenders by Nov. 19.

TENDERS RECEIVED AND ACCEPTED.

The *Aberdeen* Town Council have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of electricity meters. The Penny-in-the-Slot Electric Supply Syndicate, General Electric Co., Venner and Co., British Insulated Wire Co. and the Premier Electricity Meter Co. also submitted tenders. As announced in our last issue, the tender for house service cable has been let to the Callender Company. The British Insulated Wire Co., the Western Electric Co., Siemens Bros. and Co., the Telegraph Manufacturing Co. and W. T. Henley's Telegraph Works Co. also tendered. For the house fuse boxes the tender of Mr. Alex. Spark was accepted, and tenders were also received from the British Insulated Wire Co., the General Electric Co., the Reason Manufacturing Co. and Ernest F. Moy (Limited).

The *Ipswich* Guardians have accepted the tender of Messrs. Crompton and Co. for the supply of an electric motor for the new workhouse at £159.

The tender of Messrs. Yates and Thom has been accepted by the *St. Helens* Town Council for the supply of additional boilers at the electricity works.

The *Leyton* District Council have given out the following contracts for the supply of additional electric lighting plant:—

Dowson Economic Gas and Power Co.—Gas plant.
General Electric Co.—Dynamos.
Wells Bros. and Co.—Gas engine, piping, &c.
Laurence, Scott and Co.—Switchboards.
Fuller-Wenstrom Electric Co.—Motor.
Western Electric Co.—Cables.

APPOINTMENTS VACANT AND FILLED.

Particulars are given in an advertisement on another page of the requirements of the electricity and public lighting department of the St. Pancras Vestry, who require (1) a prime cost and third assistant clerk at a salary of £100 per annum, increasing by £5 to £120 per annum; (2) a shorthand and correspondence clerk commencing at £90 per annum, increasing £5 annually to £120 per annum; (3) a boy clerk. Forms of application for (1) and (2) can be obtained at the offices, 57, Pratt-street, and have to be returned by Nov. 19. Forms of application for (3) can be had at the Vestry Hall, Pancras-road, London, N.W.

The National Boiler and General Insurance Co. require an electrical engineer for electrical machinery insurance and general engineering work. Salary £150 to £175 per annum. Further particulars are set out in our advertisement columns, and applications must be sent to the chief engineer (Mr. Edward G. Hiller), 22, St. Ann's-square, Manchester.

The Leyton District Council require an engineer-in-charge for their electric light works. Commencing salary 35s. per week, increasing by annual increments of 2s. 6d. per week to 50s. See advertisement.

Competent wiremen are also required at Leyton. See advertisement.

A junior assistant is wanted for the meter and testing department of the Brighton Electricity Works. See advertisement.

The St. Giles and Bloomsbury (London) Guardians require an engineer, with knowledge of electric lighting work. Salary £2. 10s. per week. Applications to 57, Broad-street, W.C., by 15th inst.

The Worcester Electric Light committee will recommend the City Council, on Wednesday next, to appoint Mr. F. Harman Lewis, late of Wolverhampton, to the position of borough electrical engineer, vacant by the resignation of Mr. E. T. Ruthven Murray, who has been elected to fill a similar position at Willesden. There were 29 applications, but this number was reduced to five by the committee, whose choice ultimately rested on Mr. Harman Lewis. The salary attached to the position is £350 per annum. Mr. Harman Lewis, who was born in 1863, was educated at Epsom College for the medical profession. In 1883, Mr. Lewis gave up his medical studies, and went through a course of training in electrical engineering at the Finsbury Technical College, obtaining the college certificate. In 1886 he entered the works of the E.P.S. Company. In 1889 he was for a time upon the staff of the Westminster Electric Supply Corporation, then for about two years an assistant engineer to the St. James's and Pall Mall Company's station, and in 1891 was appointed electrical engineer to the Corporation of Hull, for

Digitized by Google

whom he designed and carried out an electricity works on the three-wire sytem at a cost of about £35,000. In 1893, Mr. Lewis went to Wolverhampton as borough electrical engineer, and has designed and laid down electricity works on the 2,000 volt direct-current system, for public and private lighting, at a cost of about £40,000.

The Liverpool City Council have appointed Mr. W. H. Collis assistant electric tramway engineer at a salary of £240 per annum. Mr. M. Pattern has been appointed motor inspector.

Mr. A. S. Black has been appointed assistant engineer at the Derby Corporation electricity works, in place of Mr. H. G. McHaffie resigned. Mr. Hugessen has been appointed mains superintendent.

BUSINESS NOTICES.

Messrs. Williamson and Joseph (Limited) have acquired the sole rights of the "Prentice" patent magnetic automatic cut-out. The firm have in preparation a revised list giving a description of these instruments, which can be obtained on application to Northampton Works, Northampton-grove, Canonbury, London, N.

The partnership business hitherto existing between Thomas Coombe Moore, George Warren and Charles Henry Mathews, electric light fittings manufacturers, &c., trading as T. C. Moore and Co., 2, Longford-street, Regent's Park, N.W., has been dissolved.

We are informed that, for the purposes of reconstruction, the British Incandescent Electric Lamp Co. has gone into voluntary liquidation, and the New British Incandescent Electric Lamp Co. has now taken over the business of the old company. The offices of the new company are at 55, Suffolk House, Laurence Pountney-hill, E.C., and the works are at Willesden, where new machinery is being put down.

It was resolved at a meeting on Oct. 17 to voluntarily wind up the Niagara Battery Co. (Limited) for purposes of reconstruction and to appoint Mr. F. Offor, 139, Cannon-street, as liquidator. This resolution has been confirmed.

BANKRUPTCIES, LIQUIDATIONS, &c.

The public examination of Jacob Gütman (otherwise Jacob Goodman), lately trading as J. Goodman and Co., was held at the London Bankruptcy Court last week. Particulars of this failure were given on p. 57 of our last issue. The bankrupt said he came from Germany in 1889, and commenced business in 1893—first at 3, Broad-street-buildings, E.C., next at 20, New Broad-street, and finally at 48, Commercial-street, E. His failure was due to loss on the trading, want of capital, and to the proposed arrangement for the discharge of his debts by the company having fallen through. Examination concluded.

A first and final dividend of 1s. 10½d. will be payable on the 17th inst. at 3, Grimshaw-street, Burnley, in the bankruptcy of J. Fletcher and J. A. Hirst, electrical and mechanical engineers, Bankfield Works, Curzon-street, Burnley, late Northgate Electrical Works, Chester, and 17, Full-street, Derby.

In the bankruptcy of E. H. Berry, electrical engineer, 22, St. Matthew-street and St. James's Hall, Burnley, the trustee (Mr. H. L. Price, 79, Mosley-street, Manchester) has been released.

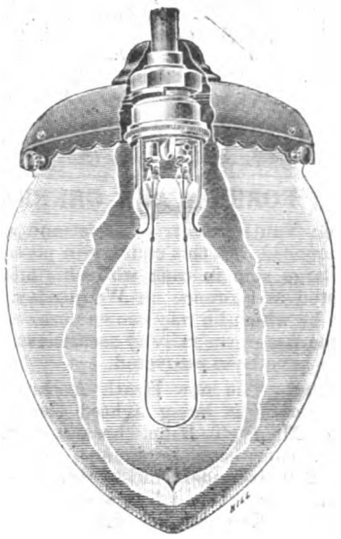
Messrs. C. S. Madan, Salford; E. C. Carter, St. Albans; and R. Stanton, the younger, London, have been appointed a committee of inspection to act with the Official Receiver and Liquidator of the Cox Thermo-Electric Co. (Limited).

In the Chancery Division, on Wednesday, Mr. Justice Wright made an order that the voluntary winding-up of the Apostoloff Automatic Telephone Parent Syndicate (Limited) be continued under the supervision of the Court.

In the Chancery Division, on Wednesday, Mr. Justice Wright said that he wished to state publicly (for the benefit of liquidators in voluntary liquidation which had been continued under the supervision of the Court), that steps would shortly be taken requiring them to make reports of what they had done. There had been about 143 cases of supervision orders since the winding-up registry had been established down to the end of 1897, and in most of these nothing had resulted. He was going to call on the liquidators in all these cases to make reports on affidavit as to the state of the liquidation and the funds in their hands, and by summonses require their attendance with reference to these matters.

Plant Catalogue.—We have received from Messrs. Drake and Gorham, 66, Victoria-street, London, S.W., their latest catalogue of electric lighting plant, which, in addition to plant, apparatus and accessories for lighting, deals with electric telephones and bells. The catalogue also contains prices of working cost and of initial outlay, specimen estimates, and a thumb index to the subjects in the book affords ready reference facilities. Before the list is sent out a charge of 1s. 6d. is made, which is refunded on receipt of first order. The demand for apparatus supplied by Messrs. Drake and Gorham has necessitated further extension to the offices in Victoria-street.

Ediswan Lamp Fitting.—We give below a sketch of a new fitting, introduced by the Edison and Swan Co. for high candle-power lamps. This fitting has been specially designed for use with incandescent lamps of 200 and 300 c.p., and is claimed to be



especially suited for outside and shop window illumination. The globe carrier is so arranged that the internal part of the fitting is not affected by damp or the weather, whilst the topmost hood of the carrier can be adjusted to admit of sufficient ventilation.

Code Telegraphy.—We have received from the Mercantile Publishing Co. (Limited), of 30, Walbrook, London, E.C., a copy of a work which has been prepared to assist those who, in the course of their business, have occasion to send and receive telegraphic messages in code. The work is called "The Official Vocabulary in Terminational Order." It will be remembered that some four years ago the International Bureau at Berne issued a not altogether satisfactory vocabulary of code words, and it was felt by many that the selected words were particularly liable to terminational error. Merchants and other code users will, therefore, welcome a work which will prove of great assistance in locating errors and mutilations where these occur in the terminational letters. In the book under review all words with similar endings are brought together. The price of the book is 40s., bound in cloth.

Society of Model Engineers.—Under this title a new society has been formed. The annual subscription is 10s. 6d., and applications for membership should be addressed to the secretary (Mr. H. Sanderson), "The Mount," Ealing, London, W.

The "Engineering Magazine."—The contents of the November issue of this magazine include "The Chinese and Recent Industrial Progress in China," by J. S. Fearon and E. P. Allen; "The Steel Foundations of the Shipbuilding Industry," by J. Riley; "Great Railway Stations of England," by T. Cargill; "Essential Elements of Economy in Steam Power Installation," by W. Cooper; "Effective Systems of Finding and Keeping Shop Costs," by H. Roland; "The Mining, Smelting and Refining of Nickel," by T. Ulke; "The Latest Improvements in the French Lighthouse System," by J. Boyer; "Continuous Operation in the Manufacture of Window Glass," by R. Linton; "The Evolution in Central Station Practice," by C. F. Scott; and "Sanitary Principles in the Construction of Isolation Hospitals," by G. A. Middleton. The usual review of the World's Engineering Press is also given. Copies of this number may be had at the offices of *The Electrician*, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.

Enclosed Arc Lamp Patents.—We have received the following extract from the *Wall-street Journal* (New York) for publication:—"In the suit of the Marks Enclosed Arc Light Co., New York, *versus* Washington Mills Co., New York, a decision has just been rendered in favour of the complainant. The suit was begun in the United States Circuit Court, Sept. 10, 1897, and the decree granted to the Marks Company by Judge Coxe on Oct. 18, 1898. The patent infringed is No. 520,996, of Marks and Ransom, dated June 5, 1894. This patent broadly covers the method of operation used in all modern enclosed arc lamps. The Washington Mills Co. were users of the Kinsman lamp, sold by the Electric Construction and Supply Co., New York. The decision peremptorily stops the sale of unlicensed enclosed arc lamps by the Kinsman Company, and also involves the payment of damages by the defendant. This decision is understood to be unfavourable to General Electric."

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and tele-

Digitized by Google

phone wire and material, but not including electrical instruments or machines, which are not separately specified) from Nov. 2 to Nov. 8, with the ports of destination :—

Argentina—Rosario, £239. *Australasia*—Adelaide, £1,148 ; Brisbane, £414 ; Launceston, £90 ; Perth, £301 ; Sydney, £655 ; Wellington, £942. *Belgium*—Ostend, £62. *Brazil*—Rio Janeiro, £65. *Canada*—Montreal, £123. *Ceylon*—Colombo, £20. *China*—Shanghai, £156. *France*—Boulogne, £17. *Germany*—Hamburg, £120. *India*—Bombay, £54 ; Calcutta, £255. Madras, £16. *Japan*—Yokohama, £2,216. *Malta*—£86. *Roumania*—Sulina, £63. *Russia*—St. Petersburg, £30. *South Africa*—Cape Town, £96 ; Durban, £775 ; East London, £351. *Sweden*—Gothenburg, £22 (telegraph material) ; Stockholm, £470. Total £8,786, against £11,464 in the corresponding week last year (Nov. 3 to Nov. 9).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Arrest.—Claude Vautin, electro-chemist and metallurgist, who, as previously announced, left this country in possession of valuable securities and a large sum in cash while his affairs are in bankruptcy, was arrested at Florence on Wednesday, travelling under one of the names by which he was known here—Charles Vaughan. It is stated that the American railway securities and a considerable portion of the cash have been recovered.

Asylum Lighting.—The new Heath Asylum, Bexley, of the London County Council is being lighted electrically under the superintendence of Mr. G. T. Hine, the architect, and Mr. A. A. Campbell-Swinton, consulting engineer. The contract, which includes about 3,200 incandescent lamps, generating plant of 300 kilowatt capacity, and two 1,500 ampere-hour batteries, has been placed with the Edmundson's Electricity Co. The lamps will be of 200 volts, connected on the three-wire system.

Barrow-in-Furness.—Applications for electric current are coming in so rapidly that already the question of extensions of the plant is being considered.

Battersea (London).—The Vestry have received a notification from the County of London Company of intention to apply for a provisional order for the district.

Brierley Hill.—The District Council has resolved to oppose all applications for provisional orders for this district, and the Lighting committee has been authorised to consult an electrical expert as to the Council itself applying for an order.

Brigg.—The District Council, which is considering the question of purchasing the gas works, has instructed a committee to report fully upon the subject of erecting electricity supply works.

Brighton.—The West Pier is to be lighted electrically, current being taken from the Corporation mains.

Bury St. Edmunds.—The Town Council have decided to adopt a modified electric lighting scheme, estimated to cost £16,000. This step has been taken owing to the attitude of the Local Government Board, who refused to sanction the original scheme.

Carlisle.—At the meeting of the Town Council last week the appointment of Mr. C. D. Burnet as borough electrical engineer was approved. The commencing salary is £250 per annum, and Mr. Burnet is to have liberty to take not more than two pupils. On the tramway question, Prof. Kennedy wrote that the alternative to horse haulage was overhead electric traction, and advised the latter.

Cheltenham.—A Local Government Board inquiry was held here on Friday into the application of the Town Council to borrow £17,000 for electric lighting purposes. The town clerk (Mr. E. T. Brydges) stated that the amount already borrowed was £68,152, and in consequence of the demand for current further extensions were necessary. The Mayor (Alderman Norman) said that in 1895-6 47,700 units were sold, the gross receipts being £1,050 ; in the following year 90,300 units (£2,040) ; in the next 140,600 units (£3,215) ; and a moderate estimate for the current year gave 204,200 units and £5,020 as the receipts. After allowing rebates and for the street arc lighting, he put the receipts for the current year at £6,600 net. There was a deficit of £622 on the first year's trading ; in the following year a surplus of £54 ; in the next a surplus of £1,262, and he put the figure this year at £3,300, sufficient to pay the whole of the interest and the annual sinking fund. The borough electrical engineer (Mr. Hamilton Kilgour) gave technical particulars, and, there being no opposition, the inquiry closed.

China.—Like the Moslems in Morocco, the Chinese are beginning to look kindly upon the developments of civilisation. Following on the establishment of a number of railways and other engineering works, we learn that the Westinghouse Electric Co., of America, has obtained a contract for the equipment of a large woollen mill at Tientsin with plant and apparatus for electric lighting and driving.

Chorley (Lancs.).—The Town Council have created a special committee to formulate an electric lighting scheme for the district.

City of London.—The Court of Common Council have referred the application of the Metropolitan Electric Supply Co. for a provisional order for the supply of electricity within the City to the Streets Committee.

The Streets Committee have been asked to consider and report upon the desirability of applying to the Postmaster-General for a licence to establish and work a telephone service either solely or in conjunction with the County Council.

From the annual report of the city electrical engineer and inspector (Mr. A. A. Voysey) it appears that, during the past year, 78 meters were submitted by consumers to the engineer for testing, and of these 34½ per cent. were slow, 22½ per cent. fast, and 43 per cent. approximately correct. The total number of arc lights in the City is 500. The lamp failures (1,468) is more than double what was the case in the previous year. The proportion of group failures and single lamp failures is reported to have increased during the year. The company has taken steps to remedy these defects. An improvement in the continuity of the supply to private customers is reported. At the end of 1896 there was the equivalent of 247.785 8-c.p. lamps connected to the company's mains, at the end of 1897 296,012.

Colliery Lighting.—Messrs. Kenneth and Co. have put down an electric lighting plant at their Mongomeriefield Colliery, Dreghorn, N.B., to provide current for lighting their brickworks, colliery, and other works and offices.

Constantinople.—The *Financial News* of the 9th inst. states that a company is being formed to acquire a concession for supp'ying electric current for light and power in Constantinople.

Derby.—The new borough electrical engineer (Mr. T. P. Wilmshurst) entered upon his duties on the 31st ult.

Diss.—The District Council has authorised the Suffolk Electricity Supply Co. to employ overhead wires in the distribution of electric current.

Dundee.—The receipts from the electricity department for the six months ended October amounted to £2,051. 8s. 7d., an increase of £467 on the corresponding period last year.

Durham.—At a special meeting of the Town Council on Monday the question of obtaining electric lighting powers was discussed. From a report by the Council's engineer (Mr. W. C. C. Hawtayne) the total cost of plant of 200 kilowatts capacity is given as £17,350 and of 350 kilowatts £2,000 additional. The gross revenue was estimated at £2,956. 12s., current being supplied at 5½d. per unit. The working costs would be £1,767. 10s., leaving a gross profit of £1,189. 2s. If the larger plant were installed, the working expenses would be £1,820, and the net profit £112. 17s. It was decided to obtain a provisional order.

Enfield.—The committee recently appointed by the District Council to consider the advisability of obtaining a provisional order has reported in favour of the proposal.

Formby (Lancs.).—A proposal to form a company for supplying electric current for both public and private lighting has been referred by the District Council to the Lighting committee for consideration and report.

Fulham (London).—The County of London Company and the House-to-House Company have notified the Vestry of their intention to apply for provisional orders for this district. The Electric Light committee is considering the notices.

Glasgow.—Electric lighting competition has, evidently, very little effect upon the consumption of gas in this city, as the Corporation are about to spend £1,000,000 in new gasworks. The electricity works were opened in 1893, but still the consumption of gas continues to increase at a rapid rate, as is shown below :—

Minimum Consumption of Gas per 24 hours in Cubic Feet.

1874	9,162,000	1894	22,853,000
1884	13,700 000	1898	31,354,000

The annual consumption has increased from 1,305,000,000 cubic ft. in 1874 to 4,800,000,000 in 1898.

Owing to the extreme satisfaction which the Mitchell-street and Springburn tramway has given, resulting in a saving of 3d. per mile on the working expenses, the Tramways committee decided on Wednesday to recommend the Council to construct an electric tramway from Glasgow Cross to Govanhill. The electric line between Parliamentary-road and the Cross is approaching completion and is to be continued to Govanhill.

Glossop.—The Town Council are to apply for a provisional order, but it has been decided to enter into negotiations with a company for a transfer of the order as soon as obtained.

Great Grimsby.—There was a further discussion by the Town Council last week of the conditions for re-leasing the tramways to the local tramways company. The lines are to be re-laid and equipped electrically, and the Corporation are to supply electric current. Subject to some slight modifications the seal of the council is to be affixed to the agreement with the company.

Halifax.—The Town Council have been petitioned to extend the electric tramways into the Greatland district. In the course of his address on Wednesday the Mayor said that the electric tramways recently instituted were proving very satisfactory, the profit for the quarter amounting to £1,336.

Digitized by Google

Hampstead (London).—The report of the Lighting committee on the formation of a special reserve fund in connection with the Vestry's electricity undertaking was presented at the last meeting. The report favoured the creation of a fund, and the committee further stated that they were strongly of the opinion that the whole of the profits arising from the undertaking should be set aside to form this fund. The recommendations were agreed to unanimously. The receipts from the sale of current for the Michaelmas quarter amounted to £3,620. 10s., compared with £2,446. 11s. 8d. in 1897.

Hastings.—The Town Council have decided to apply for powers to construct and work electric tramways. It is not, however, proposed to put down a line on the front, a proposal which has, so far, met with considerable opposition.

Heckmondwike (Yorks.).—The District Council, which has decided to engage an electrical expert to prepare an electric lighting scheme for the district, has asked three engineers to wait upon and be interviewed by the Board.

Hull.—The City Council have authorised the Works Committee to take over from the present contractor the work of constructing the new electric tramway system. The Council's works department will complete the contract.

Hythe.—The Town Council will apply for a provisional order to prevent a company from obtaining electric lighting powers for the district.

Imperial Penny Post.—The Indian Government has decided to join in the scheme for Imperial penny postage.

Islington (London).—A motion will be submitted at the next meeting of the Vestry recommending that the cost of extending the street lighting to the Shoreditch boundary be ascertained.

Killarney (Ireland).—Our readers will probably remember the long and acrimonious contest which took place two or three years ago between the electric lighting and gas interests in this town. For six months the town had the advantage of electric and gas lighting; but, owing to an informality in the contract with the Electric Lighting Company, its supporters on the Township Commission were surcharged with the cost of electric lighting. Negotiations are now proceeding for the amalgamation of both concerns and the formation of a new company to undertake both electric and gas lighting in the district.

Kingstown (Dublin).—The question of formulating an electric lighting scheme will be taken up by the new Town Commission. A provisional order was obtained by the Commission in 1896, but no attempt has been made to comply with its provisions. Notice has now been given by Messrs. Porte, Sykes and Co., of Dublin, to obtain an order. This application is to be opposed by the Commission.

Leeds.—At the meeting of the City Council on Wednesday it was reported that the negotiations for the purchase of the undertaking of the Yorkshire House-to-House Electricity Co. had been completed.

Leyton.—The electric light mains are to be considerably extended. The Electric Light committee reported at the last meeting of the Council that the additional battery of Hart accumulators had been laid down, and was now working; also that the new engine was being erected, and would be working in about a fortnight.

Light Railways.—The Tyldesley, Atherton and Leigh Rural District Councils and Lowton Parish Council have approved the proposal to connect Liverpool, St. Helens, Leigh, Wigan, Bolton and intermediate towns by means of an electric tramway system. The Leigh Urban Council have appointed a sub-committee to consider the matter.

A project for the construction of a light electric railway between Camborne and Redruth has been submitted to the Camborne and Redruth District Councils.

The Board of Trade have confirmed the order of the Light Railway Commissioners to construct a light (electric) railway between Dudley and Stourbridge.

The Board of Trade on Tuesday heard the objections to the order of the Light Railway Commissioners authorising the British Electric Traction Co. to construct a light (electric) railway between Coatbridge and Airdrie. Sir Courtenay Boyle presided. The objectors were the North British and the Caledonian Railway Companies who were legally represented. Mr. Littler, Q.C., for the Caledonian Co., said that the promoters' proposals raised a very serious question for the main line companies throughout the kingdom generally, as, in the view of the objectors, the Light Railways Act was never intended to apply to schemes like the present which was of a highly competitive character with existing railways. He took the preliminary objection that the Commissioners at the local inquiry had wrongfully refused to hear the opposing railway companies on the question of competition, and he wished the Board of Trade's decision on the matter before going fully into the merits. After discussion, it was agreed that, inasmuch as decision in favour of the company's contention would involve the remission of the order to the Light Railways Commission for rehearing, which was not desirable, the objection should be waived. Mr. Littler pointed out that the Light Railways Act was not intended to apply where the existing communications were sufficient. Communications in the Airdrie and Coatbridge districts were, he held, sufficient, for both railway companies had a large number of stations in it—the Caledonian no fewer than five, and the North British as many as six. When the act was passing through Parliament, Mr. Ritchie had stated that the proposals had reference to railways whose cost would be under £3,000 a mile, while Lord Dudley in the House of Lords had pointed out that the bill was proposed in the interests of agricultural districts, and emphasised the fact that it provided that the Board of Trade required that schemes affecting existing railways should be submitted to Parliament by bill. Mr. Littler argued that the present was a case that came clearly within section 9 of the Light Railways Act, particularly within sub-section 3 of that Act. He went on to point out that the order proposed to give the company power to carry goods, and as the line was laid out the promoters would be in a position to form connections with public works now served by the existing railway companies. For the North British Co. Mr. Balfour Browne pointed out that their line directly paralleled the proposed line for a considerable distance along the canal, and that between the North British line and the proposed line there were situated works that yielded many thousands of pounds per year to the North British. If this light railway were made, it would be possible for the promoters to abstract much of that traffic. He went on to contend that to all intents and purposes the present proposals were tramway proposals under the Act of 1870, and as such ought to come before Parliament. Evidence was given by prominent residents that a feeling existed in the district in favour of the tramways and that a considerable portion of the present traffic could not be accommodated by the facilities provided by the railway companies. Provost Sharp, of Coatbridge, said there was a strong feeling in the district in favour of the light railways scheme. Ex-Provost Connor said he had called a meeting in connection with the opposition of the railway companies to the order, and he had never in the whole of his public experience seen a more unanimous feeling in support of any proposal. Mr. Sidney Morse, for the British Electric Traction Co., addressed Sir Courtenay Boyle in support of the order. He contended that what was proposed was a light railway, which would serve traffic which was not at present accommodated, and could not be accommodated, by the existing railways, and consequently could have no effect on these railways. Mr. Littler and Mr. Balfour-Browne maintained that the application was one for a tramway in the guise of a light railway, and they asked that the order should not be confirmed by the Board of Trade, because, as an application for a tramway, it should go before Parliament in the shape of a bill or provisional order. Sir Courtenay Boyle intimated that he would take time to consider, and would report to the Board of Trade on the preamble. The decision will rule the Broughty Ferry and other orders, which the railway companies object to on the ground of competition.

Liverpool.—The inquest upon the lad William Strong, who was killed in jumping off an electric trailer car at Liverpool last week, resulted in a verdict of accidental death, the jury adding a rider as follows:—"We think that it would be advisable to have lifeguards in front of the wheels of the trailer cars as well as in front of those of the motor cars."

London County Council.—At Tuesday's meeting the Finance committee reported on an application from the Hampstead Vestry for a loan of £51,343 for electric lighting purposes for the parish. It was agreed to advance £10,491. It was also agreed to loan the Islington Vestry £6,785 for similar purposes.

The telephone question was then discussed, to which reference is made on another page. In reply to the discussion which followed, in which reference was made to the success achieved by Glasgow in its application for a licence, Mr. J. W. Benn said he could only deplore the fact that Glasgow had succeeded in getting its licence, while, as far as London was concerned, they were unfortunately no forwarder. It was now five years since the Council first took up the question of the telephone service, and the delay in the settlement of the question was a very serious matter for London. The cities in the provinces were mostly getting the service for 10 guineas a year, and if they took £12 as the average rate for London, it would be found that the citizens of the metropolis were paying £50,000 or £60,000 more a year for the telephone than they ought to be doing. The National Company, in order to secure the monopoly it now enjoyed, had to purchase some 13 other companies, and upon going into figures he found that London had to pay the dividend on the watered capital consequent upon those purchases. The purchase of those 13 companies cost the National Company £3,000,000, and after carefully dividing the expenditure into what he might call the constructional part, and that which represented the watered section he found that the former represented £1,800,000 and the latter £1,400,000. In order to pay 6 per cent. upon that watered capital the company had to raise

Digitized by Google

£83,000 a year, and if justice was done London only ought to be called upon to provide £17,000 out of that sum, but as a matter of fact London had to find no less than £76,000 every year to pay dividend on watered capital. A large number of persons were anxious to get upon the telephone in London even at the present price, but they were told that they could not have the service because the Council had refused to give the National Company facilities in respect to underground wires. That, however, was not the fact. The real truth was that they were prepared to give consent in all such cases provided that the company would place them upon like terms with Manchester, Leeds, Liverpool or other places in respect to charges. He could only hope that the block which at present prevented a fuller use of the telephone in London would shortly be removed, and if that recommendation were passed all possible pressure would be put upon the Postmaster-General in order that London might not much longer be placed at such a serious disadvantage with provincial cities.

On the subject of electric tramways Mr. Benn said a letter had been received from the London United Tramways Co. in which the Directors said that, provided they could obtain the consent of the Board of Trade, they would be prepared to carry out, as an experiment, an underground electric system on the Hammersmith section, if the Council would enlarge the scope of its resolution so as to include the working of the Goldhawk-road section by the overhead system, and would extend for seven years the purchase period with respect to the lines. They further suggested that the Council might sanction the use of the overhead system on the Goldhawk-road section, in addition to Uxbridge-road, leaving the Hammersmith branch entirely out of the question for the present. This letter would be taken into consideration at the next meeting of the Highways committee.

Llanelly.—The District Council have received a communication from the Local Government Board pointing out that, as nothing has yet been done to comply with the terms of the Llanelly provisional order (1891) it devolves upon the Board to say whether the order shall be allowed to remain any longer in force. Before taking action they invite the Council's explanation of the delay.

Maidstone.—The Town Council have engaged Messrs. Kincaid, Waller and Manville to prepare a report on the electric lighting and refuse destructor project, at a fee of 50 guineas.

Manchester.—A special meeting of the City Council is to be held on the 16th inst. to approve the proposed omnibus bill to be promoted next session, in which powers are sought for the better lighting of culs de sac, the development of the electric light undertaking and the working of telephones under licence from the Post Office.

Marylebone (London).—Last night the Vestry discussed a special report from the Electric Lighting committee, which stated that they had good reason to believe that the Board of Trade would not grant them a provisional order to supply the parish with electric light, and they therefore recommended that the committee have power given to it to obtain a private bill to enable the Vestry to supply the parish with electricity. Mr. Brooke Hitching, C.C., moved the adoption of the report, and Mr. White pointed out that the Vestry could not instruct its solicitor to take preliminary steps to obtain the act until, first of all, the Vestry had discussed the question and decided whether they would go for the proposed act or not. They could not decide such a question without 28 days' notice being given that such a question was to be discussed. Several members urged that action should be taken at once, or else the Vestry would have to wait another twelve months. The report was ultimately adopted by 40 to 7.

Mill Lighting.—Messrs. Alexander Cowan and Sons, papermakers, Valleyfield, Penicuik, N.B. (and London) have recently put down new plant for the electric lighting of the whole of their large establishment. The installation, which has been carried out by Messrs. Lowdon Bros., is said to be the largest in any papermaking works in Scotland. The plant consists of a 100 H.P. engine and three shunt-wound continuous-current dynamos. The lighting is effected by means of 36 2,000 c.p. arcs and about 1,000 incandescents of from 16 to 50 c.p.

Municipal Honours.—In the published list of mayors for the year 1898-9 the names of the following gentlemen connected with electrical and engineering enterprise (either municipal or private) appear :—Ald. Geo. Norman, chairman of the Electric Lighting committee at Cheltenham ; Ald. W. Bruce (re-elected), chairman of the Electric Lighting committee at Sunderland ; Ald. H. Coltman, of H. Coltman and Co., engineers, Loughborough ; F. T. Garrett (re-elected), of F. T. and A. Garrett, Dunstable ; W. Oulton, chairman of the Electric Tramways committee at Liverpool ; Sir W. Crundall, chairman of the Dover Electricity Supply Co. ; and H. M. Julian, of H. M. Julian and Sons, Basingstoke.

Nelson.—The Town Council have decided to apply for power to construct a light (electric) railway from the terminus of the Burnley and district tramways to the boundary of Colne.

Northallerton (Yorks).—A company has been formed for the purpose of erecting electricity supply works in this town. The question of public electric lighting is to be considered by the District Council.

Paisley.—The Town Council have authorised the Electric Lighting committee to enter into negotiations for the acquisition of additional land for the extension of the electricity supply works.

Police.—At the Westminster (London) Police Court on Friday, John Limbrey Higgs, of Delahay-street, Westminster, appeared to an adjourned summons charging him with having committed perjury in his examination in respect to the liquidation of the I.E.S. Accumulator Co., of which he was a director. Further formal evidence was submitted, and the summons was adjourned for a fortnight.

Provisional Order Notices.—Official notice of intention to apply for provisional orders has been given by the Bermondsey and Plumstead (London) Vestries, the Hartlepool and Longton Corporations, the Runcorn and Walker District Councils, and the Weston-super-Mare and District Electric Light and Power Syndicate for Weston-super-Mare.

Rathmines (Dublin).—A Local Government Board inquiry was held on Monday into the application of the Township Commissioners to borrow £50,000 for electric lighting purposes. The secretary (Mr. F. P. Fawcett) appeared in support of the application, and gave particulars of the scheme and of the expenditure involved. The consulting engineer (Mr. Robert Hammond) gave technical details. There was no opposition.

The Township Commissioners have received Mr. Robert Hammond's report on the electric lighting tenders.

St. Helens.—As announced in another column a new company entitled the New St. Helens and District Tramways Co. (Limited) has been formed for the purpose of acquiring the tramways in St. Helens. The lines are to be equipped electrically by the Corporation, and are to be worked on lease by the new company.

St. Pancras (London).—The Vestry has decided to increase the salary of the chief electrical engineer (Mr. Sydney W. Baynes) from £600 to £700 per annum. This figure is to be afterwards increased to £800 by two annual increments of £50. The question of revising the salary of the chief clerk of the electricity and public lighting department is at present under the consideration of the Electricity committee. The Vestry has also decided to make some additions to the clerical staff, and particulars of the requirements of the department are set out in an advertisement elsewhere.

Sale.—Some time ago the Electric Lighting committee applied to the Manchester Corporation for terms for supplying current in the Sale district. Apparently matters have drifted, and the policy of the committee does not commend itself to some members of the Council. Mr. Wells, the chairman of the committee, however, recently defended the course that had been adopted. Great strides were, he said, being made in electrical engineering, and the committee were anxious to move forward with caution. He thought the wisest course was to consult an expert and obtain estimates for a scheme of their own. The chairman of the Council thought that, if they were to wait for every possible improvement in electric plant and apparatus, they might wait for ever. The committee's proposal was approved.

Sleaford (Lincs.).—The District Council have complied with the request of the Tradesmen's Association and have appointed a committee to arrange with the Association for the erection of electricity supply works.

Southport.—The Town Council are applying for a provisional order enabling them to adopt electric or other form of mechanical traction on the local tramways. The scheme involves an expenditure of about £60,000.

Tanfield (Yorks).—At the meeting of the District Council last week it was decided to enter into an agreement with a company for the electric lighting of the district.

Telephone Municipalisation.—In their applications to Parliament for power to establish and work a telephone system, the Glasgow Corporation are seeking powers, not only for the City of Glasgow, but also for the neighbouring burghs and districts comprised within the counties of Lanark, Renfrew, Dumbarton and Stirling, as far west as Paisley and Renfrew, as far south as Mearns, as far north as Kirkintilloch and Kilsyth, and as far east as Rutherglen.

The Lord Provost's Committee of the Edinburgh Town Council resolved on Wednesday to recommend the Council to apply for Parliamentary powers to equip and work a telephone exchange system.

Waterloo (Liverpool).—The District Council have entered into an agreement with the Liverpool Overhead Railway Co. for constructing and working a system of electric tramways in this district. The Council will obtain the necessary Parliamentary powers, construct the permanent way, and lease the lines to the company. The company will pay the cost of obtaining the order, and will provide the electrical equipment.

Digitized by Google

Watford.—In a report by Mr. W. C. C. Hawtayne on the progress of the electricity supply works it is stated that the station will not be completed before the end of January, and the Council will probably be in a position to undertake the supply of electric current continuously by the end of February. High-street, Queen's-road, and St. Albans-road are to be lighted by means of 40-c.p. incandescents on columns, placed 50 yards apart, and two arc lamps are to be erected in the market place and one in the station-yard as an experiment.

Wath (Rotherham).—A provisional order is to be obtained by this District Council.

West Hartlepool.—The Mayor has announced that, as the plans for the electricity supply works had not given satisfaction, it had been decided to invite Prof. Kennedy to visit the borough, and prepare plans for a scheme, similar to that at Sunderland and at a similar cost. It was also reported that the General Electric Tramways Co. had consented to the use by the Council of the tramway poles for supporting arc lamps.

Whitechapel (London).—The Electric Lighting committee recommend the District Board of Works to purchase Messrs. Ind, Coope and Co.'s premises in Osborn-street, for £10,000, as a site for electricity supply works.

Workhouse Lighting.—The Islington (London) Guardians have decided to put down an independent electric lighting installation at their infirmary in St. John's-road, Holloway.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

October 27, 1898.

22,578. E. RUSHTON and R. E. GRIFFIN. Cleethorpes. A new or improved method of bonding or connecting rails used for electrical traction and the like.

22,599. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in electric meters. (C. D. Haskins, United States.)*

22,600. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in incandescent electric lamps. (G. B. Painter, United States.)*

22,601. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in electric arc lamps. (H. C. Spinney, United States.)*

22,603. F. M. LONG and E. SCHATTNER. London. Improvements in prepayment electricity meters.

22,622. Q. MARINO. London. Improvements in or relating to electrolytic baths.

October 28, 1898.

22,664. E. M. MUNRO, H. BRECKNELL and H. J. ROGERS. Bristol. New or improved appliances for use in securing the copper bonds or conductors in electric tramway rails.*

22,683. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in couplings for electric conductors. (F. E. Case, United States.)*

22,697. H. D. WIBRATTE and A. F. LANASPÈZE. London. Improvements in apparatus for regulating the intensity of electric currents.

22,699. W. B. SAYERS, H. A. MAYOR and MAYOR AND COULSON (LIMITED). London. Improvements in dynamo and electric machines.

22,700. H. EDMUNDS. London. Improvements in the manufacture of tubes or conduits, or the like, more especially intended for containing electric cables or conductors.

October 29, 1898.

22,728. B. H. THWAITE. London. Improved means for effecting the collection and transmission of high-potential electricity.

22,729. B. H. THWAITE. London. Improvements in methods having for their objects the electrical propulsion of tramway cars and other vehicles, and in apparatus therefor.

22,762. C. E. B. HOLT and A. J. TAYLOR. Bradford. Improvements in the method of and apparatus for indicating and arresting the speed of electric tramway cars and the like vehicles.

22,777. C. FELDMANN. London. An improved light distributor or reflector for electric incandescent lamps.

22,794. J. D. F. ANDREWS. Fulham. Improvements in electric railways or tramways.

22,799. F. H. DAVIES and R. S. DRAYCOTT. London. New or improved method of and means for switching on and off the electric current in surface contact systems for electrically-propelled vehicles, and safety "cut-out" for same or other surface contact systems.

22,802. L. J. STEELE, Sir J. B. MAPLE, BART., and J. VERITY. London. Improvements in or connected with reflectors for incandescent electric and other lamps.

22,803. L. J. STEELE, Sir J. B. MAPLE, BART., and J. VERITY. London. Improvements in or connected with incandescent electric lamps.

October 31, 1896.

22,820. J. ENRIGHT. London. Improvements in the means of propelling tramcars by electricity.

22,836. H. SIMON. Manchester. Improvements in electric switches.

22,858. E. E. PRESTWICH and L. N. BURT. London. Combined apparatus for regulating the supply of electricity to lamps, motors, and other electrical apparatus.

22,870. S. B. APOSTOLOFF. London. Improvements in electricity meters.

22,872. J. LOISELET. London. Improvements in electrolytical apparatus.

22,884. E. ANDREAS. London. Improvements in or relating to means for making electrical connections.

November 1, 1898.

22,936. BAIRD and TATLOCK. Glasgow. An arrangement to act as a meter for one or more electric lamps, the object being to register the time during which the lamp or lamps burn.

22,964. A. VANDAM and T. H. MARSH. London. Improvements in plug switches or wall contacts for electric circuits.*

22,987. A. STUTTMANN. London. Improvements in electric arc lamps.

23,000. C. D. ABEL. London. Automatic regulator for electric currents. (F. Back, Austria-Hungary.)

November 2, 1898.

23,043. J. A. FLEMING. London. Improvements in the construction of electrical resistance balances or bridges.

November 3, 1898.

23,143. W. BUCK. London. Improvements in electrical warming pans and like articles.

23,155. H. H. LEIGH. London. Improvements in electric rail brakes and electromagnets therefor. (Gesellschaft zur Verwerthung elektrischer und Magnetischer Stromkraft (System Schiemann and Kleinschmidt) Ad Wilde and Co., Germany.)

23,160. A. SCHLATTER. London. Improvements in transformer switches.*

November 4, 1898.

23,183. W. H. STURGE. Birmingham. Improvements in electrical switches.

23,207. W. H. LOCK, J. PLACE and M. BARR. London. Improvements in electrical heating and melting, specially applicable to the metal pots of linotype machines.

23,233. J. WETTER. London. Improvements relating to electric railways and tramways provided with sectional conductors or surface contacts. (The Elektrizitäts-Aktiengesellschaft-vormals Schuckert and Co., Germany.)*

23,234. J. WETTER. London. Improvements in or connected with electric railways and tramways provided with sectional conductors or surface contacts. (The Elektrizitäts-Aktiengesellschaft-vormals Schuckert and Co., Germany.)*

23,243. P. RIBBE. London. Improvements in and relating to electric accumulators.*

23,249. C. H. PRESTON. London. An improved primary battery for generating electricity.

November 5, 1898.

23,265. E. J. PRESTON. London. Improvements in glow lamps and holders.

23,306. C. LEVETUS. Leeds. Improvements in or relating to galvanic batteries.

23,307. C. LEVETUS. Leeds. Improvements in or relating to galvanic batteries and the like.

23,320. F. W. GOLBY. London. Electromagnetic safety apparatus for lifts, mining cages and the like. (W. Suermondt, Germany.)

23,334. A. PELOUX. London. Improvements in electricity meters for continuous and alternating currents.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1897.

16,220. BELL. Electrically-illuminated signs, advertising media, or the like.

16,428. WHITE and WHITE. Method of and means for employing electric traction on ropeways, railways and like means of transit.

23,267. BRYANT. Apparatus for the electro-deposition of one metal on another.

23,304. WOOD. Magnetic circuit arrangements for dynamo electric machines and other purposes.

23,530. STUART and FORD-MOORE. Bicycle holders or stands and their combination with electrical contact makers.

23,625. WHEATLEY, JAMES and BROWNE. Electrical time-switch.

24,829. SIMPSON. Coin-freed mechanism applicable to gas, electricity and like meters.

25,403. BOULT. (Anderson and Anderson.) Current-collectors for electric railways.

26,646. THE BRITISH THOMSON-HOUSTON CO. (LIMITED) and HOLDEN. Watt-hour meters and in the means for damping in same.

27,261. PRICE and JOHNSON. Covers, caps and lids for closing the entrances of gas, sewer, telephone and electrical supply shafts and holes, gullies and the like.

27,380. SELLICK. Electrical cut-outs and fittings.
27,387. MARTIN. Electro-therapeutic exercising apparatus. (Date applied for under International Convention, May 10, 1897.)
27,725. LEITNER. Construction of accumulators or secondary batteries.
27,805. WATSON. Electric lamp-holders.
27,806. WATSON. Electrical switches.
27,807. WATSON. Manufacture of switches for electrical purposes.
27,875. SOAMES. Electric lifts, hoists, capstans and the like.
28,458. HOFFMANN. Electrically-controlled submarine mines.
28,839. WOOD. Trolleys used on overhead wires for electric traction.
28,960. STAVELEY and PARSONS. Pushes for electric bells and the like.
29,062. SMITH and GRANVILLE. Apparatus for the manufacture of electric cables.
29,390. SIEMENS BROS. AND CO. (LIMITED), and HOLDEN. Electrical apparatus for transmitting and receiving predetermined messages.
29,676. BLACK. Union box for electric mains for lighting, traction power or other purposes.
30,447. SIEMENS BROS. AND CO., LIMITED (Siemens and Halske Actien Gesellschaft). Supplying electrical energy to railways worked by alternating currents.

1898.

3,806. SWOBODA. Apparatus for making and breaking electric circuits at predetermined times.
8,441. JÄGER. Electric recording system for navigational purposes.
9,466. BRANT. Electric switch.
11,604. STASSANO. Electro-metallurgic production of iron, steel and their alloys with chronium tungsten, nickel, manganese and the like.
13,274. THE BRITISH THOMSON-HOUSTON CO, LIMITED (Steinmetz) Generators for use in systems of electrical distribution.
17,161. MCMILLAN. Automatic electric switches.
17,583. BUGG and DARLING. Electric batteries.
18,137. STENDEBACH. Contact apparatus for electric railways with underground current feed and partial conductors.

COMPANIES' MEETINGS AND REPORTS.

Venezuela Telephone and Electrical Appliances Co. (Limited).

A meeting of this Company was held on Friday, at 28, Victoria-street, Westminster, Sir DOUGLAS FOX presiding. The CHAIRMAN expressed the satisfaction of the Board in being able to announce that the Company had been making good progress. For the twelve months ended June 30 the accounts showed a profit of £9,942, to which had to be added £744 brought forward. After providing the interest on the First and Second Debentures, &c., and the dividend on the Preference shares, there remained £5,499, and the Directors recommended a dividend on the Ordinary shares for the year to June 30th at the rate of 4 per cent. per annum, absorbing £2,800; that the balance of the discount and expenses of the First Debenture issue, amounting to £1,500, should be written off; that £500 be put to reserve and £699 be carried forward. The capital outlay for the year was £1,754 against £8,423 for the previous year. At June 30, the number of subscribers to the Company's instruments was 2,640. The Preference dividend of 8 per cent. and the Ordinary of 4 per cent. were approved.

Western and Brazilian Telegraph Co. (Limited).

The report of the Directors of this Company for the half-year ended June 30, to be presented at the thirty-sixth ordinary general meeting to-day (Friday), states the total earnings for the period amount to £72,692. 13s. 10d., against £59,754. 17s. 8d., an increase of £12,937. 16s. 2d. compared with the half-year to June 30, 1897. The working expenses were £39,376. 7s. 9d., against £44,575. 12s. 4d., a decrease of £5,199. 4s. 7d. Including the amount brought forward (£1,428. 5s. 11d.), and the dividend received upon the shares held in the "Platino" Company, the balance to credit of revenue is £44,914. 2s, from which has been deducted £8,041. 12s. 5d. interest on Debentures and Debenture Stock, £2,016. 3s. for tax, and £1,078. 17s. 8d. has been invested on account of the Debenture Stock redemption fund, £8,000 has been placed to reserve, leaving a balance of £25,777. 8s. 11d. The Directors now recommend the payment of 5s. per share, free of tax, for the half-year on the Ordinary shares (at the rate of £3. 6s. 8d. per cent. per annum), against 3s. per share (£2 per cent. per annum) for the corresponding period of last year, leaving a balance of £1,427. 18s. 11d. to be carried forward. In the case of shares divided into "preferred" and "deferred," this 5s. per share will be payable, 3s. 9d. to the preferred and 1s. 3d. to the deferred shareholders.

The shareholders of this Company having consented to exchange more than the number of shares required under the agreement between this company and the Brazilian Submarine Telegraph Co., the agreement has become operative as from June 30 last. In consequence, directors of the Brazilian Submarine Company have become directors of this Company and *vice versâ*, and Mr. W. S. Andrews, chairman of this company, has been elected chairman of the Brazilian Submarine Company. Mr. W. H. Axworthy has been appointed manager of the company, and Mr. E. Steer Hodson, formerly traffic accountant, has been named secretary in place of Mr R. M. Cunningham, who has retired. The arrangement now made will conduce to the more harmonious and efficient working of the companies, and will prove advantageous to the Governments and the public.

NEW COMPANIES, STATUTORY RETURNS, &c.

BUTE ELECTRICAL MANUFACTURING CO. (LIMITED).—This company was registered on Nov. 2, with a capital of £5,000, in £1 shares, to enter into an agreement with the Electrical Insulation Syndicate (Limited), and Augustus J. Marquand, and to acquire, develop, work and deal with certain inventions. The first subscribers (each with one share) are:—H. B. Marquand, T. McM. Heywood, F. G. Treharne, A. J. Marquand, engineer; E. Jenkins, G. Chitham and T. H. Owen, engineer. The first directors are:—H. B. Marquand, T. McM. Heywood, F. G. Treharne and A. J. Marquand.

DRUMMOND ART METAL WORKS (LIMITED).—This company was registered on Nov. 2, with a capital of £5,000, in £1 shares, to acquire and carry on the business of electrical engineers and metal workers carried on by Whitehouse and Thomas (Limited). The first subscribers (each with one share) are:—C. J. Toy, J. A. Campbell, T. H. Toy, W. A. Low, L. E. Reitz, A. J. Woods and F. C. Collyer, jun.

DUTTON AND CO. (LIMITED).—This company was registered on Nov. 7, with a capital of £21,000, in £1 shares, to acquire the business of Dutton and Co. (Limited), incorporated in 1889, and to carry on the business of mechanical engineers, electricians, and manufacturers of and dealers in railway and other signals, locking, safety and detecting apparatus, electrical and other lamps, dynamos and all kinds of electrical and magnetic apparatus. The first subscribers (with one share each) are: Ralph H. C. Nevile, J.P.; Charles Dutton, signal engineer; William Buck, engineer; S. T. Dutton, engineer; S. G. Corkran, G. W. Bull and Mrs. M. F. Nevile. The first Directors are: C. A. S. Murray, S. G. Corkran, Ralph H. C. Nevile and S. T. Dutton.

HAMILTON, MOTHERWELL AND WISHAW LIGHT RAILWAYS CO. (LIMITED).—This company was registered on Nov. 3, with a capital of £20,000, in £10 shares, to construct, lease, or otherwise acquire any light railways or tramways in Hamilton, Motherwell and Wishaw, in the county of Lanark, and to equip, maintain and work by electricity, or any other power, all light railways or tramways belonging to the company. The first subscribers (each with one share) are: N. J. Ferdinand, Ernest Lazarus, John T. Merz, H. F. Charles, A. Clements, W. Martindale, and A. R. Monks.

NEW ST. HELEN'S AND DISTRICT TRAMWAYS CO. (LIMITED).—This company was registered on Nov. 4, with a capital of £150,000, in £5 shares, to acquire the undertaking of the St. Helen's and District Tramways Co. (Limited), to construct, maintain, and work any tramways and railways, to carry on the business of cable and wire mauufacturers, electricians, mechanical engineers, suppliers of electricity, and to carry on the business of an electric light company in all its branches. The first subscribers are: Sir J. A. Willox, M.P., T. Evans, Jacob Atherton, D. L. Chalmers, H. Martin, J.P., James B. Atherton and F. J. Leslie. The first directors are: Sir J. A. Willox, M.P., T. Evans, H. Martin, James B. Atherton and Jacob Atherton.

SMITH, THOMSON AND CO. (LIMITED).—This company was registered on Nov. 3, with a capital of £2,000, in £1 shares, to carry on the business of electrical, gas and general engineers, machinists, millwrights, manufacturers of machinery, boilers, dynamos, engines, &c.

WEST KENT ELECTRICITY SUPPLY CO. (LIMITED).—This company was registered on Nov. 2, with a capital of £20,000, in £1 shares, to construct, lay down and fix all necessary cables, wires, lines, accumulators, lamps and works, and to carry on the business of electricians, mechanical engineers, suppliers of electricity and manufacturers of electrical apparatus. The first subscribers (each with one share) are:—W. W. Pritchard, J. T. Rockett, H. G. Pulham, G. H. Davies, G. W. Sutton, H. M. Carpenter and W. May.

DRAKE AND GORHAM ELECTRIC POWER AND TRACTION (PIONEER) SYNDICATE (LIMITED).—The statutory return to Aug. 30 gives the nominal capital as £20,000, in £10 shares, of which 1,107 have been taken up. £3 per share has been called.

ELECTRIC LIGHT AND POWER CO. (LIMITED).—The statutory return to Aug. 10 has been filed. The capital is £6,000, in £1 shares (of which 5,000 are Deferred). Seven shares have been taken up and the full amount paid.

ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS (LIMITED).—According to the statutory return to Sept. 7, the capital is £150,000, in £5 shares, of which 16,087 have been taken up. £2 per share has been called, and £32,174 received. £11,079 has been paid in advance of calls.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 28¾d. per oz. (Nov. 10). Consols (2¾ per cent.) 109⅞—110 for money, 110—110¼ for account; 2½ per cent. 104½—105 (Nov. 10). Stock Exchange Settling Days: Consols, Dec. 1; Stocks and Shares Continuation Day, Nov. 28; Ticket Day, Nov. 29; Pay Days, Nov. 11 and 30; Mining Share Carry-over Day, Nov. 26.

BORDEAUX TRAMWAYS AND OMNIBUS CO. (LIMITED).—A meeting of this company will be held on the 17th inst., to confirm the special resolution relative to the sale of the undertaking to the Cie Française des Tramways Electriques et Omnibus de Bordeaux and to the agreement with the French Thomson-Houston Co.

CARBON MANUFACTURE IN RUSSIA.—In Lyons the Banque Privée Rüsse has formed a company, entitled the Société Française pour la Fabrication des Electrodes, with a capital of 1,000,000fr. This is the first

Digitized by Google

French works for manufacturing carbons for electrical purposes, which have hitherto been imported, notwithstanding exorbitant duties.

CHELSEA ELECTRICITY SUPPLY CO. (LIMITED).—During the week this company invited subscriptions for £40,000 Four and a-Half per Cent. Debenture Stock at £108. 10s. The lists opened at 10 a.m. on Tuesday, and (owing to the large number of applications) were closed at 2 p.m. on Tuesday instead of 4 p.m. on Wednesday.

COMBINATION OF GERMAN ELECTRICAL FIRMS.—It is reported that an arrangement has been made for amalgamating the undertakings of the Ludwig Loewe Aktien Gesellschaft (of Berlin) and the Elektricitäts Aktien Gesellschaft vormals Schückert and Co. of Nuremberg. The arrangement is, however, subject to the approval of the shareholders of both companies. The Loewe company increases its nominal capital from 7,500,000 marks to 40,000,000 marks (from £375,000 to £2,000,000), and offers to the shareholders of the Schückert company in exchange for each 2,000-mark Schückert share one 1,000-mark Loewe share and 100 marks in cash, The Schückert shareholders have also an option over one Loewe share at par. The shares of the subsidiary Schückert Company (the Continentale Gesellschaft für Elektrische Unternehmungen) amounting to 26,000,000 marks (£1,300,000) will be exchanged into shares of the subsidiary Loewe Co. (the Gesellschaft für Elektrische Unternehmungen.) The latter will increase its capital from 30,000,000 to 50,000,000 marks (£1,500,000 to £2,500,000), and the project of increasing the capital of the Union Electrical Company, which is also controlled by the company will be abandoned. The Disconto-Gesellschaft, the Dresdner Bank, the Bank für Handel und Industrie, and the firm S. Bleichröder are all said to be interested in the combination.

CUBA SUBMARINE TELEGRAPH CO. (LIMITED).—A dividend at the rate of 6 per cent. per annum and a bonus of 2s. per share on the Ordinary shares, both free of tax, for the half-year ended June 30, is declared.

ELMORE COPPER COMPANIES.—"A Poor Shareholder," having written to the papers complaining of the outlook for shareholders in the Elmore companies, has drawn the following characteristic reply :—

"'A Poor Shareholder' has taken the altogether unnecessary trouble of calling himself an utter fool. Surely the very fact of his having addressed so absurd a letter to the press at a time when he knows, or could very readily know by applying to the officials of the companies, that a large sum of money is about to be put into the business by a particularly strong group of financiers, is amply sufficient to proclaim him chief of the tribe he so much aspires to. One might be more inclined to believe in the *bona fides* of this 'Poor Shareholder' did he but have courage enough to attach his name and address to his letter. Might I ask if he does not hope to convert the poverty he advertises into comparative affluence by acting as the cat's-paw of those whose only object is to frustrate the amalgamation of the Elmore companies."—A. S. ELMORE (Leeds).

Another correspondent ("W. O.") complained of the delay in calling a meeting and placing the true position of affairs before the shareholders, and of a great waste of the capital of the company. To this Mr. J. Shurmer (a director) replies :—

"The letter of 'W. O.' would not have drawn a reply from the directors were it not that some shareholders might suppose that the statements it contains have some foundation in fact. It is simply monstrous to talk of the directors having 'wasted' between £150,000 and £200,000 of the company's money, when the utmost that can be truly said is that the securities held by the company have depreciated to a large extent, these securities being shares or debentures in other companies with the management of which the directors of the Foreign Elmore company have nothing to do. The assets of the company at December, 1893, stood at £52,783, of which £18,879 is due to the fact that the share capital of the German company has been reduced from £2 to £1 shares, and £39,864 has been written off the investments, subject to which it follows that there has been a gain during the above period over and above the working expenses ; moreover, the liabilities have been reduced by £5,221. How preposterously reckless, then, are 'W. O.'s' misstatements ! But I suppose it is not the object of 'W. O.' and his colleagues to state the truth. No promises have been made by the Directors of 'great things in store ;' but they adhere to their belief that the position of their securities is improving steadily, and that the future of the Elmore process is assured."—J. SHURMER (London).

A Mr. T. H. Butt lets further light upon the latest developments in Elmores. He writes (from Headingley, Yorks), that :—

"If 'A Poor Shareholder' had taken the trouble to have written to the secretaries of the companies he would doubtless have been informed that an agreement exists between the directors of the various Elmore companies to complete the amalgamation which has been in contemplation for some time past, and, further, that an agreement exists under which one of the most influential financial houses in London and Paris guarantees the new amalgamated Elmore company a total subscription of £300,000 in cash. From my knowledge of the matter I am convinced that when worked with the ample capital which is now being provided the Elmore process will prove at least as great a commercial success in this country as it has proved in France since sufficient capital has been available there for the purchase of raw material."

"A Poor Shareholder" and "W. O." appear to have succeeded in extracting some information which will interest many besides themselves. How is it that the Elmore shareholders find it necessary to "extract" their information in this way ? Some boards of directors keep their shareholders informed of negotiations likely to improve the value of their property.

STOCK EXCHANGE NOTICE.—Application has been made to the Stock Exchange committee to appoint a special settling day and to grant a quotation to the Four per Cent. Preferred Ordinary "A" shares of £10 each, and Five per Cent. Deferred Ordinary "B" shares of £10 each of the Great Northern and City Railway Co.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Nov. 4 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £2,876.

NOTES.

Two so-called experimental electric tramways, viz., those of the Corporations of Liverpool and Glasgow respectively, are described in two illustrated articles in our issue this week. It is only in a special sense that these lines can be regarded as of an experimental nature. The overhead trolley system, *per se*, requires no further demonstration of its practicability; that has been abundantly proved by its success in tens of thousands of miles in other countries, and in considerably over a hundred miles in the United Kingdom. Nor was it necessary to show that the British contractor could supply efficient plant and equipment, or that the British public could appreciate his efforts. Wherein lies the experimental character might, then, be difficult to discover. It is undoubtedly to be found only in the hesitation of the local authorities to expend large sums of money on a general equipment of their tramway systems until they shall have first tried the overhead trolley for themselves on short lengths of their own lines. British caution is the sole explanation; and those who know well what the overhead system can do will have no doubt that these two experiments are the precursors of an immediate adoption of that system over the whole of the tramways of these two important cities. The example thus well set will speedily be followed by local authorities all over the United Kingdom.

MUNICIPAL tramway working may itself, however, be in the nature of an experiment, the success of which it may require many years to demonstrate; but that is not a matter of electric traction. Since truth and sweet reasonableness are often found in a happy medium, it is probable that the most suitable solution of the tramway problem may lie—not, on the one hand, in company ownership, nor, on the other hand, in municipal working—but in the form of ownership and management about to be given a trial at St. Helens. This particular solution, far from being new, however, has yielded some of the best results financially that has been obtained on tramways abroad. It consists in a species of dual control—the local authority owning and leasing the lines, and supplying electrical power, and a Company being granted powers to work the lines with rolling stock provided by that Company, and to control the operation and financial affairs of the system. At St. Helens a lease of 21 years has been granted to the Company, which will obtain electrical energy from the Corporation supply at 2d. per unit for the first 400,000 units per annum, and 1d. per unit exceeding this consumption.

AN instructive table showing the relative costs and profits of electric, cable and horse tramway traction in New York, for the year ended June 30 last, is published in the November number of the *Street Railway Journal*, of that city. The table is based on the official cost sheets of the Metropolitan Street Railway Co. It will be borne in mind by our readers that while horse and cable traction have been in extensive use in New York for many years, the introduction of the cable conduit system on the lines in question is of recent date. The long experience in handling cable and horse equipment, therefore, might render severe criticism of any shortcomings of the later system unjustifiable. Fortunately, leniency in this direction would be superfluous, for the superiority of electric traction, on its own merits, is placed beyond question. The total operating expenses per car-mile were 8·21d. for cable haulage and 8·98d. for horse cars, but only 5·12d. for the electric conduit system. These figures include power costs, transportation or traffic expenses, maintenance and general management; but capital charges are omitted, though if included would probably still further improve the showing in favour of electric traction. A still better result is shown by the three months' working ended September 30th last, the figures being 8·78d., 8·99d. and 5·03d. respectively.

NOR did this low cost of electric traction arise from the electric cars having shirked their due share of the work, as will be seen when we compare the ratios of the expenses to

Digitized by Google

the receipts. With the cable cars, the operating expenses were 47 per cent. of the total passenger receipts, with horse-cars the percentage was 63 per cent., while with the electric cars the low ratio of only 38 per cent. was attained. Success so marked will not fail to afford encouragement to electric traction engineers, nor will its significance be overlooked by the numerous local authorities and tramway companies upon whose minds it is gradually dawning that electric traction is *facile princeps* among tramway systems.

THE human element must always introduce uncertainty and risk into engineering operations, and the handling of a trolley car is no exception. The lamentable accident which took place on the Bradford tramways on September 19th last has been made the subject of a careful inquiry by Major CARDEW, on behalf of the Board of Trade; and in the report just issued he states that "although the accident was in great measure due to the inexperience and injudicious action of the driver and conductor, in his opinion they both did their duty to the full extent of their skill and ability." Major CARDEW recommends the continuous use of a slipper brake on the dangerous gradient, and a limit not exceeding six miles an hour in descending it. An abstract of the report is given in another column.

AN important legal decision affecting contractors is reported in our Legal Intelligence column this week. Payment to engineering contractors is commonly made by instalments regulated by the stages of progress of the work. In the case referred to a second 40 per cent. instalment became due when the work had been completed, but payment of this was refused because the plant had not passed the engineer's tests. The case became complicated by the refusal of the clients—the Corporation of Bedford—to agree to any arbitrator other than their own engineer. The judgment of the High Court was that the Corporation must agree to the arbitrator appointed by the court below.

MR. H. E. KERSHAW, the Chairman of the Electricity Committee of the Shoreditch Vestry, has just issued a pamphlet setting forth a brief statement of the dust destructor and electric lighting accounts for the year ended June 24 last. As the statement lacks the detailed completeness of the Board of Trade returns, it is difficult to know how much credence to attach to the claim that a profit of £3,184 has been made. We notice, however, that whereas the revenue from the sale of current to consumers was £8,254, the revenue from current sold to the ever-useful dust destructor was as much as £586, or equal to about one-sixteenth of the outside revenue. Nor did the utility of the dust destructor stop at this handsome contribution to the coffers of the electricity department, for it has apparently also paid an unpublished proportion of the engineer's salary. We shall deal with the matter more fully in our next issue.

The Houllevigue Prize.—The Académie des Sciences has awarded the Houlevigue prize of £200 to M. Branly, the discoverer of the coherer.

The Royal Society.—Among the Papers down for reading yesterday was one by Prof. Smithells, H. M. Dawson and H. A. Wilson on "The Electrical Conductivity and Luminosity of Flames Containing Vaporised Salts."

Cable Interruptions and Repairs.—

	Date of Interruption.	Date of Repair.
Bissao—Bolama	Aug. 3, 1898 ...	Nov. 17, 1898
St. Louis and Noronha	Oct. 17, 1898 ...	—
Pernambuco—Ceara	Oct. 19, 1898 ...	—
Ceara—Maranham	Nov. 15, 1898 ...	—

The New German-Swedish Telegraph Cable.—The new telegraph cable between Germany and Sweden has been laid by the Telegraph and Maintenance Co.'s s.s. "Britannia." The cable, which was made by Messrs Felten and Guilleame, is 70 miles long and contain four conductors.

Obituary.—It is with regret that we announce the death of M. Nicolas Jules Raffard, best known to electrical engineers in this country through the type of absorption dynamometer bearing his name. M. Raffard was one of the pioneers of electric traction, having already in 1881 designed the first accumulator tramcar built in France, and some inventions in connection with direct-driven cars are also due to him. He died on Nov. 1 at the age of 74.

Errata.—In "Electricity Works Accounts," in this issue, the following corrections should be made in the table at the bottom of p. 116: The last figure under "Revenue" should read 4,846 instead of 4,946, and the last figure under "Expenditure" should read 5,688 instead of 5,788. The figures under "Expenditure" in this table represent the total expenditure, including the sums carried to the sinking fund and paid as interest on loans.

Gift to Owens College.—Alderman John Hopkinson, the members of his family, and near relatives, have offered to the Owens College, in memory of the late Dr. John Hopkinson, a gift of £1,600 to cover the expense of building the dynamo house connected with the new physical laboratory. It is hoped that by additional contributions from friends, who desire to see a suitable memorial to Dr. Hopkinson in Owens College, where he was a student for three years, it may be possible to complete and equip the annexe, containing, in addition to the dynamo house, a number of rooms devoted to electrotechnics, and that the whole may be known as the "Dr. John Hopkinson Electrotechnical Laboratory."

The Institution of Junior Engineers.—On Saturday, Nov. 12, a party, numbering over 120, visited the site of the Lombard-street station of the northern extension of the City and South London Railway. The feature which naturally attracted the greatest interest was the work connected with the underpinning of St. Mary Woolnoth Church, immediately underneath which the main shaft for the lifts has been sunk. The large oblong shaft is 73ft. 6in. by 24ft., divided into five bays in which will work electric lifts made by Messrs. Easton, Anderson and Goolden. It is lined with cast-iron segments for a depth of 52ft. from the top, the remaining 28ft. being brickwork, in which are formed the entrances and exits to and from the lifts. The two station tunnels are 21ft. diameter and lined as usual with cast-iron rings.

Motor-Car Clubs.—The Automobile Club of Great Britain and Ireland, with which is now incorporated the Self-Propelled Traffic Association, held a dinner on Monday last to commemorate the second anniversary of the Locomotives on Highways Act, which came into force on Nov. 14, 1896. Mr. R. W. Wallace, Q.C., the chairman of the Club, presided, and among those present were Mr. G. Shaw Lefèvre, Sir Hugh Owen (permanent secretary of the Local Government Board), Mr. J. W. Swan, and several members of the Automobile Club de France.——The third annual meet of the Motor-Car Club took place on Monday morning in Whitehall-place, the run being to Sheen House, as last year. The majority of the vehicles taking part in the run were driven by oil motors, but there were some electrically-propelled cars, the total number of automobiles taking part in the procession being about 80.

Another Proposal for a Railway up Mont Blanc.—*Electricity*, of New York, states that a French engineer, of Marseilles, has suggested a plan which he considers feasible for reaching the top of Mont Blanc. The scheme contemplates the building

Digitized by Google

of a rack railway from what is known as Les Houches, a station on the line of the Geneva-Chamounix Railway, to a plateau on the side of Mont Blanc, at an altitude of 6,888ft. The line would have an average grade of 60 per cent. It is proposed to propel the trains electrically, utilising a waterfall on the upper Arve for the necessary power. From this point he proposes to run a tunnel into the mountain, which would have a rise of 600ft. in 18,864ft., and would terminate at a point 7,500ft. above the sea level. The final section of this novel railway is to consist of an elevator in a vertical shaft from the end of the tunnel to the summit of the mountain.

The Late Dr. John Hopkinson and Mr. Latimer Clark.—At the meeting of the Institution of Electrical Engineers on the 10th inst., the president (Mr. J. W. Swan) made some feeling remarks upon the great loss the Institution has sustained by the death of two of its most prominent members and past-presidents, Dr. John Hopkinson and Mr. Latimer Clark. He spoke of the valuable work done by both, referring to Mr. Latimer Clark as one of the pioneers of ocean telegraphy, who held a place of the highest honour in the records of the Institution and in the memory of its members. We quote also the following tribute to Dr. Hopkinson:—"What can I say of his character more than that it was in perfect symmetry with his work? Simple, unpretentious, sedate, honest and self-possessed; everyone trusted John Hopkinson; trusted him implicitly and without any misgiving. No man ever carried so great a weight of learning so lightly. Like the athlete he was, he did the heaviest work without any sign of effort. We must mourn that we shall see the face of these dear old comrades no more, and that the precious work they did cannot be added to."

A New Paris Tramway.—Like the London County Council, the municipal authorities of Paris have set their face against the introduction of the trolley. The line from Aubervilliers to the Place de la République runs only as far as the fortifications on the trolley system, but a new line from Charenton to the Bastille has now actually brought the trolley wires within the gates of the city. The length of the line is 8·8 miles, and it is all on the overhead trolley system, with the exception of two sections, aggregating half a-mile, on which the underground conduit is employed. Three Thomson-Houston compound-wound generators (one serving as reserve), each of 150 kilowatts capacity, furnish the power. These are driven through belting by single cylinder Farcot non-condensing engines. The station pressure is 550 volts. Three semi-tubular Meunier boilers, with a heating surface of 6,500 sq. ft., furnish steam at 100lb. per square inch pressure. These boilers work under forced draught on M. Prat's system, and a chimney 56ft. high is found amply sufficient. There is a battery of 250 cells, with a capacity of 350 ampere-hours, used for supplying the conduit sections of the line which are electrically isolated from the remainder. The battery is charged by one of the generators, a special switch being provided to short-circuit the series windings. The track is double throughout, made up of 90lb. rails with Falk cast-welded joints. In nearly all cases the posts supporting the trolley wire are in the centre of the street, and span wires are not used. The posts each carry two 5-ampere arcs on brackets, the lamps being connected five in series across the terminals of the battery. The conduit part of the lines is similar to that in use in Ninth-street, Washington, with a slot 1in. wide. There are in all 18 cars, with single-reduction motors, and differing but little from the usual Thomson-Houston construction. We are indebted to the *Industrie Electrique* of November 10th for the above particulars.

Interruptions to Supply.—A slight interruption to the electricity supply to one circuit at Tunbridge Wells took place one day last week. An earth developed on a consumer's installation, and his fuse not blowing, the transformers were overloaded. New transformer fuses were inserted and the supply was resumed from half-an-hour to 1½ hours of the occurrence. About 600 lights were affected.

At Woking the supply to about three-quarters of the total number of consumers was interrupted from 7 p.m. on Wednesday to 5 p.m. on Thursday, last week, through the failure of a pair of vulcanised rubber mains. The cables in question had been laid in earthenware pipes under an unmade road, and it is surmised that they suffered last week by the process of making the road. Difficulties were experienced in removing the cables, and the fact that Wednesday was "early-closing" night, and that a new cable-way was in process of construction, decided the engineer-in-charge to await making a re-connection till Thursday afternoon, by which time the new cable-way was finished and new cables drawn in.

At Manchester, on the 10th inst., at 8:25 p.m., a dead short-circuit was experienced, the locality of which could not be discovered for an hour. During this time the pressure could only be maintained on one out of the four circuits. The plant was kept running the whole time, and was not shut down. The exact position of the fault could not be discovered until later in the evening, and while seeking it the faulty portion of the network was again connected, causing, unfortunately, another interruption in the supply at 9:45 p.m., lasting 15min. or 20min. The short-circuit was a very severe one, four out of the five conductors being in contact, yet no damage was done either to the plant or to the roadway.

Half of the arc lamps for the Dublin street lighting remained extinguished all Tuesday night. A similar thing has happened on more than one occasion in Dublin during the last few months.

Earth Returns and Electrolysis.—Two recent Papers, one read by Mr. A. A. Knudson before the American Institute of Electrical Engineers, and the other presented to the Municipal Improvement Association at Washington by Mr. H. P. Brown, give details of extensive, and in some cases quite unexpected, damage done by currents leaking from rail return-circuits. Mr. Knudson, in his Paper, gave particulars of an "electrical survey" he had made in the Manhattan borough of New York City. Differences of potential of from ½ to 8¾ volts were detected between the rails, water-pipes, the iron structure of the elevated railway, &c., and in some cases the rails were positive to the pipes, while in others the reverse was the case. On inspection of the rails of one of the lines, it was found that a large amount of metal had been removed by electrolysis, and that the bottom sides of the rails had been "cut by the current down to knife edges," for several feet back from the ends, the edges being irregular in shape and somewhat jagged in appearance. The tie-rods of this line, originally 1½in. wide by ⅜in. thick, had been nearly all so eaten away that the middle part was missing. Mr. Brown had found that in Dayton, Ohio, cast-iron pipes had been seriously injured by stray currents. Tests showed that the pipes in the business portion of the city, 1½ to two miles from the power house, were positive to the rails, the highest readings being 4½ volts. Near the power house, however, the pipes were as much as 9 volts positive to the rails. The corrosion of the pipes at Dayton Mr. Brown attributes to a reaction of the soil surrounding them, when a current passes through it. A tar paint seems to be no protection whatever, the surface of the pipe being changed into a soft black material resembling graphite, and easily cut with a knife, this material being a conductor instead of more or less an insulator, as is the oxide, the adherent moulding sand and the tar paint usually surrounding the pipe. Chemical analysis of the soil showed that it contained carbonate and chloride of sodium.

A New Controller Governor.—On account of the general disregard by motormen of rules and regulations for handling the controllers, and the consequent waste of current, an ingenious controller governor or retarding device has been developed at the repair shops of the Chicago City Railway Co. The *Street Railway Review* describes the apparatus as follows:—"The mechanism occupies so small a space that it can be placed within any controller case between the top of the drum and the hood of the case, and it requires only the removal of a cam from the main drum shaft. The frame of the device carrying the entire mechanism is a small malleable iron casting held in place by two machine screws tapped into the back of the controller case. On the main drum shaft is a ratchet wheel having 12 notches, and a hole in the hub affords a stop in place of the cam removed. On the frame is a lever escapement with two pawls, one pawl being always engaged. Two springs, one a ½in. and the other a ¼in. closed coil spring,

Digitized by Google

hold the pawls in place in the notches of the ratchet wheel. Connected to the lever escapement is a link attached to a plunger of a dash pot 1½in. in diameter and 1½in. deep. The piston is ¾in. thick, with two iron packing rings. When the controller handle is turned one notch the air in the dash pot is compressed and holds the pawls firmly in position so that the handle cannot be turned another notch. In the bottom of the dash pot is a very small hole into which projects a needle-pointed screw, by which the area of the hole can be regulated. As soon as the air escapes, one of the springs acts and frees a pawl so that the controller handle can be turned another notch. The time occupied by this action depends entirely upon the size of the hole in the dash pot. If it is large the air escapes rapidly and frees the pawl quickly, but if it is small, the reverse is the case. By means of experiments, the size of the hole can be nicely determined and the operation of the controller is automatically regulated. It is impossible for the motorman to turn the controller handle faster than the predetermined rate."

Some Amusing American Tramway Data.—We quote the following figures from an amusing article in the *Street Railway Review* on the "greatness and possibilities" of the electric railway. Every day the street cars in the United States carry as many passengers as there are inhabitants in Greater New York, Chicago, Philadelphia and Boston. To purchase the street railways would take all of the $525,000,000 of gold, the $120,000,000 of silver, the $400,000,000 of certificates, the $225,000,000 of National bank notes and the $250,000,000 of United States Treasury notes in circulation. If the street railways were to be sold the sum realised would easily pay the debt of the United States. A fair estimate of the paying passengers carried by the street railways per annum would be 2,660,000,000, and this would be increased by 50 per cent. if the transferred passengers were included, which, in the aggregate, represents two rides for every inhabitant of the globe, and tells its own story when compared with the 535,000,000 carried annually on the 182,000 miles of steam road in the States. No less than 33,000,000 sleepers have been placed in the road beds, and the track rails, if placed end to end, would reach around the equator, leaving enough over to extend as an axis from the north to the south pole. These rails weigh 3,500,000 tons, and represent the entire output of the rolling mills of the United States for two years. It is estimated that the power stations have an aggregate capacity of 525,000 H.P., and consume per annum 2,300,000 tons of coal, evaporating 3,300,000,000 gallons of water. To operate the present street car equipment would require 320,000 horses, which, if harnessed two abreast, would form a solid procession extending from Chicago to Cleveland; but to transport the passengers carried by electric cars in the slower-going horse cars would necessitate one-third more cars than now, and this would extend the line of animals to 480 miles. The average electric car travels 120 miles a day; each one of its wheels makes 84,500 revolutions, and in the course of a year passes over 8,000,000 rail joints; yet with all this constant wear and opportunity for accident from breakage, a passenger is as safe on a trolley car as in the retirement of his own home. Only one in 28,000,000 passengers is killed, and only one in 800,000 is injured in any way; and if a man were to spend his time on the street cars waiting for a chance to present a damage claim against the Company, he would have to travel one hour a day for 31 years, and spend $1,180 in car fare before he would be hurt. Before his time for being killed would come he would be a patriarch of five and a-half centuries, having been continually on the cars day and night.

The London County Council and the Telephone.—A letter signed by Mr. W. E. L. Gaine, the General Manager of the National Telephone Co., and published in *The Times* of Nov. 11, states that to whatever extent the London telephone service may be inefficient or inadequate at the present time, is entirely the fault of the London County Council:—

In May, 1896, the Company applied to the County Council for the consent of that body, as required by the Telegraph Act, 1892, to enable the Company to place its wires underground—the only solution of the serious difficulties which otherwise beset the Company from the use of overhead wires. Prolonged negotiations followed, and finally terms were agreed and embodied in a series of resolutions passed by the County Council on June 1, 1897. . . . The draft of the formal agreement was . . . submitted to the Company for consideration on January 29, 1898. It was then found that two additional conditions not forming part of the bargain had been inserted. These conditions were—(1) That the Company should make a wayleave payment to the County Council which would impose a burden upon the Company amounting to several thousand pounds per annum, and (2) that the Company should reduce its tariffs to an arbitrary scale as fixed by the County Council, which would involve the Company in an immediate loss of revenue of upwards of forty thousand pounds per annum. The Company considered that the importation of these conditions after more than twelve months had been spent in concluding the bargain was not in accord with good faith. The Company replied that . . . it was willing to make wayleave payments . . . if the County Council indemnified the Company against any claims which might be made by the road authorities in the Metropolis, and, as regards tariffs, it . . . offered to agree to fix the Company's present tariffs as the *maximum* charges to be made, and to come under an obligation to supply all intending users equally and without undue preference. On May 19, 1898, the County Council broke off the negotiations. . . . On the 3rd inst., there were 992 people in London waiting to be joined up to the Company's system. As regards the bulk of these they will have to wait an indefinite time, on account of the difficulties in the way of the Company in physically connecting their premises with its exchanges owing to the want of facilities which it is in the power of the County Council to give. . . . I see that it was stated in the course of the debate that the Highways Committee is prepared to recommend the requisite facilities being given to the Company, if the Company will concede to London similar terms as to tariffs and wayleave payments as the Company has given to Manchester, Liverpool, and other towns. The position of London is not comparable with that of any other town. It covers an area of 634 square miles. The working cost of a telephone system throughout this great area is nearly double what it is anywhere else, and the tariffs must therefore be proportionately higher. At the same time I may add that the Company is considering whether it cannot meet the requirements of small users and those requiring a more limited service. It is the intention of the Company to invite the County Council to re-open negotiations, and it will not be the fault of the Company if a proper arrangement is not come to. Let me give one instance of the treatment to which the Company is subjected. When the bargain was concluded with the County Council on June 1, 1897, the Company was allowed to go on with certain portions of underground work which were very urgently needed. Amongst the works authorised is a system of pipes for upwards of 6,000 miles of wires which the Company has laid down in the districts governed by the Holborn Board of Works and the Vestry of St. Giles, all centring upon a large exchange of the Company situate at the corner of Holborn-viaduct and St. Andrew-street. These pipes are stopped close to the north-west corner of Holborn-viaduct, and for months they have been lying idle . . . because the Company cannot obtain from the local authority the permission to carry them across one road and into the exchange.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, November 18th.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7.30 p.m. Second General Meeting of the Session in the Literary and Philosophical Society's Lecture Hall, Newcastle-on-Tyne. Paper to be read: "Repairs to Iron and Steel Vessels in way of Boilers and Stokeholes," by M. W. Aisbitt.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting, when the following Paper will be read: "Liquid Air: A Short Description of its Production and Summary of its Application to the Chemical or other Industries," by Cecil Lightfoot.

MONDAY, November 21st.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture I.—"Acetylene," by Prof. Vivian B. Lewes.

TUESDAY, November 22nd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting, when the following Paper will be further discussed: "Electrical Transmission of Power in Mining," by W. B. Esson.

WEDNESDAY, November 23rd.

SOCIETY OF ARTS.

8 p.m. Second Ordinary Meeting. Paper to be read: "Long Distance Transmission of Electric Power," by Prof. George Forbes, F.R.S.

THURSDAY, November 24th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when Prof. Silvanus P. Thompson's Paper on "Rotatory Converters" will be further discussed.

FRIDAY, November 25th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Papers to be read: (1) "On the Properties of Liquid Mixtures," by R. A. Lehfeldt; (2) "On certain Diffraction Fringes as applied to Micrometric Observations," by L. N. G. Filon.

LIVERPOOL CORPORATION ELECTRIC TRAMWAYS.

The history of the development of the electric tramway scheme at Liverpool is well known to our readers, but we may briefly mention that on the acquisition of the horse tramway system of that city it was brought prominently before the Corporation that the service would be greatly improved by conversion to the overhead trolley system. Dr. John Hopkinson was appointed consulting engineer to report on the proposed scheme, and ultimately the overhead trolley system was recommended for a short length of what has been termed an experimental line. Upon the death of Dr. Hopkinson last August, Mr. John Brodie, the city engineer, and Mr. A. Bromley Holmes, the city electrical engineer, were appointed the joint engineers to complete the electric line, which is now on the point of being opened, these engineers, of course, working in co-operation with the representatives of the late Dr. John Hopkinson.

In adopting a system of electric traction for the tramways the Liverpool Corporation has departed somewhat from the practice initiated at Leeds, and subsequently adopted at Glasgow. In the last two places the tramways are driven from an independent power station, whereas at Liverpool the tramway generating plant is erected in the same station as the Corporation electric lighting plant; and, although separate generators are used, and are driven by separate steam engines, the management of the generating plant is the same, and identically the same steam boiler plant is used. Liverpool, therefore, affords the first example of a municipal combined electric lighting and tramway system, the lighting and tramway departments being owned and worked by the Corporation.

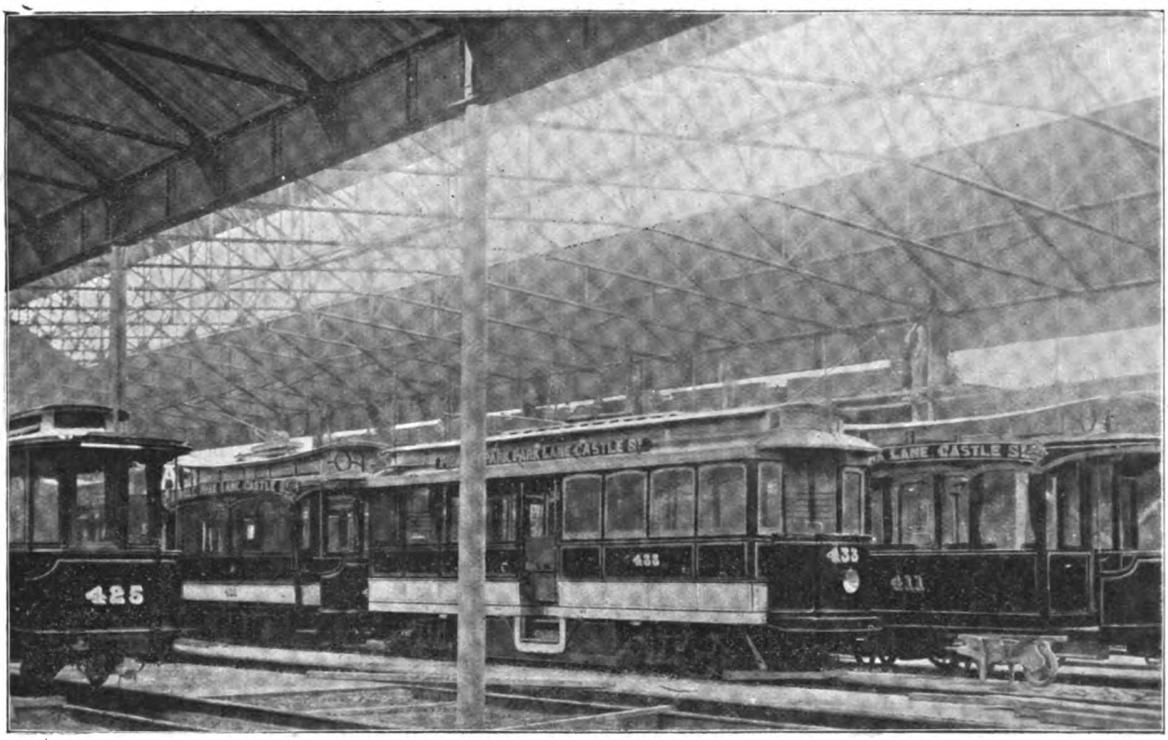
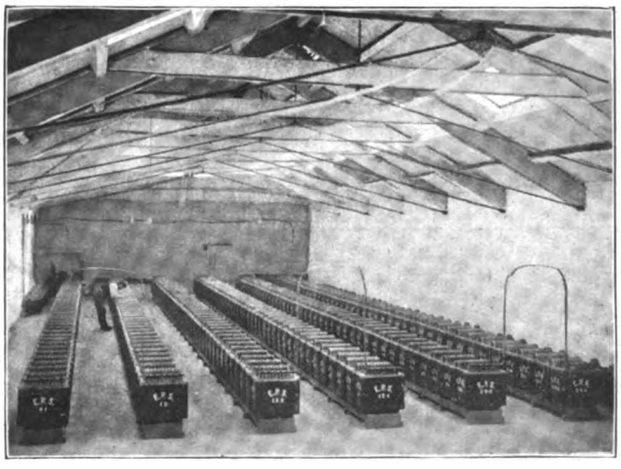
The experimental line extends from a point near the old Post Office to Prince's Park and to the Dingle, as shown on the accompanying map. The route is largely undulating, and has many steep gradients but few awkward curves. The pilot cables are lead-sheathed and armoured. The feeders are laid on the solid system in iron troughs, similar in all respects to those exclusively used in Liverpool for the last 10 years for the ordinary electric supply. The pilot cables con-



Interior of Car Sheds, showing various types of Motor Cars and Trailers for Liverpool Corporation Electric Tramways.

entire length of the track is 6¼ miles, principally double. It is equipped partly on the centre pole system, but principally on the span wire system, with side poles erected along the pavements. The trolley wires, which are duplicated throughout, are of 0·4in. diameter hard-drawn copper wire of circular section. They are placed centrally with respect to the track, the trolley poles being of the centre under-running type, commonly used in America. The overhead trolley system, which has been constructed by Messrs. Robert Blackwell and Co., is divided into sections of about half-a-mile in length,



Battery Plant erected by the E.P.S. Co. for Liverpool Corporation Tramways.

and is fed at two points shown on the map. The feeder cables are 0·4 sq. in. section, and provide for both the supply and pilot return. These were supplied by Callender's Cable and Construction Co., and are of their well-known vulcanised bituminous dielectric type, while the Board of Trade

ist of three-core 7/18 conductors, with fibrous insulation, lead-covered, armoured with steel tape and yarned. The route of the mains is as follows (as shown on the map). Start-

nected to the rails, and two of the cores in one of the three-core cables are laid through the pillar-box for telephonic purposes. Proceeding along Park-lane the two remaining feeders and the two three-core armoured cables are laid as far as the corner of Park-place and Upper Warwick-street, at which point the feeders are finished off in the pillar box. Similar connections, as at Paradise-street, are here made for telephonic purposes, and also at Duncan-street, in Park-lane. From Upper Warwick-street the armoured cables are alone continued, the one to the car sheds at the Dingle and the other to the end of Princes-avenue. At the rail head, at both Princes-avenue and also at Dingle, one of the conductors in the three-core armoured cable is connected to the rails, and the other two are used for telephonic purposes. Provision is also made for telephoning from the pillar box at Haliburton-street. The Board of Trade wire is intact from the generating station to the rail head in each of the two routes, one for Dingle and the other for Princes-avenue. The telephone circuit is a series one, and the conductor is arranged to form one continuous loop, traversing the whole route, into which the instruments may be inserted at the points mentioned above. The vulcanised bitumen feeders are laid through from

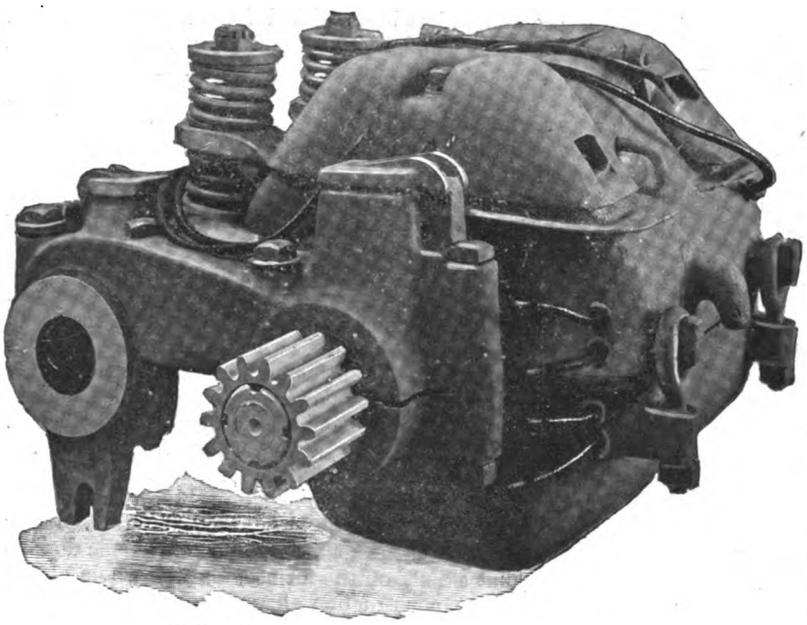
Digitized by Google

the station to the feeder points without any intervening boxes, the lengths of the two being to Park-lane 180 yards, and to Upper Warwick-street 1,840 yards. The lengths of the two Board of Trade pilots are: to Dingle 3,560 yards, and to Princes-avenue 3,200 yards. The total length of the telephonic circuit is some 17,200 yards.

At the Dingle terminus well-equipped car sheds, capable of housing 50 cars, are now in course of completion. At the far end of these sheds there is a single traversing table, capable of handling one car at a time. There is also a fan rail system at the other end of the sheds. The sheds are provided with workshops for small repairs, and with inspection pits and arrangements for handling motor trucks.

The deputation which visited the Continent and America, prior to the adoption of electric traction by the Liverpool Corporation, decided to make an all-round experiment with various types of motor cars. Accordingly, at first, one American and one German car were ordered, and subsequently 14 additional American motor cars and 14 German motor cars. The various types of car are shown in one of the accompanying illustrations. The American cars are of the double bogey type, similar to those used in Cleveland, Ohio. They were supplied by Messrs. Dick, Kerr and Co., and are fitted with Brill maximum traction trucks and with Walker motors and trolley equipment, each car having two 35 H.P.



Walker Tramway Motor built for Spring Suspension.

Walker motors, controlled on the series-parallel system. The German cars are of two kinds: the "Altona" type and the "Ringbahn" type, as used on the Hamburg tramways bearing these names. Both types of cars are carried on rigid trucks, and are equipped with two 20 H.P. Schuckert motors together with Schuckert series-parallel controllers. There are, in addition, 15 German trailers. Each of the American cars is capable of carrying 40 passengers, while the German motor cars have a capacity of only 20 passengers and the trailers 18. One car is fitted with a Standard air brake, the air pump being worked off one of the axles and the pump automatically cut-out when the pressure in the air vessel reaches the maximum amount, which is capable of slight adjustment. This brake actuates the same brake blocks on the car as the hand brakes, and is found to work very satisfactorily. Electric emergency brakes are fitted to all the cars.

The power station plant for this tramway consists at present of three Willans-Siemens 300 H.P. generators, together with a 150 ton E.P.S. battery. The engines are of Messrs. Willans and Robinson's I.I.I.S. type, and differ in no way from the ordinary pattern except that they have considerably heavier fly wheels than are used for the lighting sets. In the illustration the tramway generators are the three nearest in the long line of generators shown. The engines are of the compound triple-crank type and work non-condensing. They are coupled to two-pole 550-volt shunt dynamos, built by Messrs. Siemens Bros. and Co., having smooth-wound armatures of the drum type. The regulating resistances for the shunts are carried on the side of the generators. The normal speed of the generating sets is 350 revolutions per minute. In addition to these three generating sets, larger tramway generators of 1,500 H.P. each are now in course of construction, and will be erected before the tramway system is extended. These were described briefly in an article in *The Electrician*, Vol. XL., p. 786, but the following additional particulars may be of interest. The engine is of the three-crank compound type, fitted with Willans automatic expansion gear, and is designed to run at 230 revolutions per minute, developing a normal load of 1,250 H.P. under a pressure of 160lb.; but for short periods a load of 1,500 I.H.P. may be allowed. The effective area of each high-pressure cylinder is 277 sq. in., and of each low-pressure cylinder 854 sq. in.; the stroke is 16⅞in., and the diameter of crank shaft 11in., the shaft being of Siemens-Martin mild steel. The overall height of the engine is 19ft. 4in., and the floor space, including the generator, to which the engine is to be direct-coupled, 24ft. by 13ft. 6in. The engines are so designed that they may be converted into triple-expansion engines with the least possible trouble. The variation of speed, from full load of 780 kilowatts to one-eighth load of, say, 96 kilowatts, is guaranteed not to exceed 2 per cent., and from full load to no load 3 per cent. The dynamo to which this engine is coupled is a Siemens multipolar continuous-current generator of the type known as 10 B 84/15, and will develop 1,420 amperes at 550 volts. The set is not provided with a separate flywheel, the necessary weight being located in the armature.

The tramway switchboard is independent of the lighting switchboard, and is placed immediately opposite the three tramway sets. It consists of a cast-iron frame carrying three marble panels, the left-hand one being the main board, the middle the booster board, and the right-hand the Board of Trade board. Upon the main board are mounted four double-pole switches and single-pole fuses for connecting three dynamos and one battery to the tramway 'bus bars; and two Chamberlain and Hookham electric meters, one of which is connected to the battery circuit and works in either direction. There are also on this panel one recording ammeter in the battery circuit, one automatic circuit-breaker, two single-pole switches, one of which is for disconnecting the near rail and the other the near trolley, one voltmeter for reading the potential across the 'bus bars, and one ammeter in the circuit of the near rail. The capacity of all the switches is 300 amperes, but the circuit-breaker is adjusted for 500 amperes normally, and is capable of being adjusted to 800 amperes. The booster board has mounted upon it two single-pole two-way switches of the throw-over type for connecting the line feeder and the track feeder direct to the 'bus bars or to the 'bus bars through the booster; also two single-pole main switches, one for disconnecting the distant rail and for the distant trolley wire. There is also an ammeter on this panel. The capacity of all the instruments and switches is 300 amperes. The Board of Trade panel has the usual equipment on it, viz., one recording ammeter reading to 10 amperes, one low-reading ammeter with two scales of 0·0005 to 0·005 and 0·05 to 5 amperes. This instrument is connected across the terminals of the circuit-breaker on the main board. On this panel there is a spring contact switch and fuse provided for the ammeter, also two low reading recording voltmeters. The instruments on this switchboard were made by Messrs. Elliott Bros., and the switchboard was constructed and erected by the Electric Construction Co.

The Electric Construction Co. are now building a special E.C.C. booster for the tramway supply. This combination consists of three E.C.C. upright bipolar type machines, mounted rigidly together in line. The centre machine is a

Digitized by Google

shunt-wound 500-volt motor, the outside machines being generators of the series-wound type, giving a potential at any speed proportionate to the current up to a maximum of 300 amperes, the magnet coils of the generators being in series with one of the armatures. The motor is provided with the usual starting resistance, and has also a rheostat in the shunt coils for slight adjustments.

The battery is erected on the floor of a spacious room adjoining the machinery room. It consists of 246 cells, manufactured by the Electrical Power Storage Co., each cell containing 21 plates of the K.L.P. type, the battery being rated at a maximum discharge of 480 amperes at 550 volts for one hour.

The total cost of the construction and equipment of the 6¼ miles of tramway in this experimental line is estimated at £82,000, viz., £33,000 for the line construction and equipment, £24,000 for the total of 45 cars, and £25,000 for the car sheds and workshops. It is proposed to charge 2d. for a seat in the non-smoking section and 1d. in the smoking section of the car, for a complete single journey.

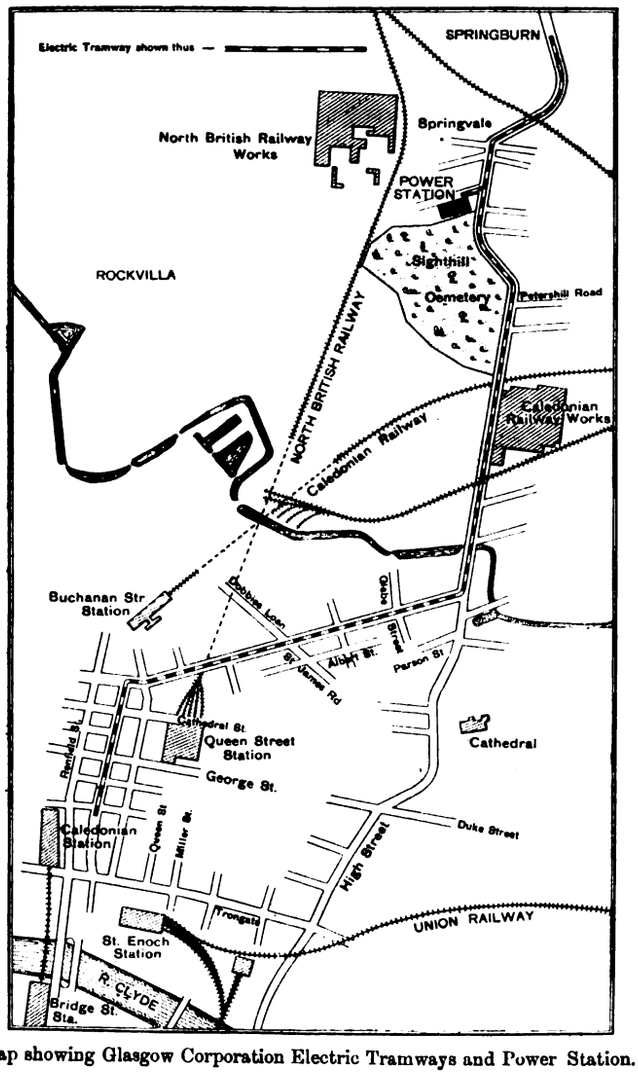
Following is a list of the principal contractors and manufacturers who have supplied plant or carried out work on these tramways:—

Complete equipment of lines.	Robert Blackwell and Co.
Cars, motors and controllers (American)	Dick, Kerr and Co.
Do. (German)	Busch and Co.
Motors & controllers (German)	Schuckert and Co.
Cables	Callender's Cable and Construction Co.
Engines	Willans and Robinson.
Dynamos	Siemens Bros. and Co.
Booster	Electric Construction Co.
Switchboard	Electric Construction Co.
Instruments	Elliott Bros.
Battery	Electrical Power Storage Co.

We have pleasure in acknowledging our indebtedness to Mr. A. Bromley Holmes, the Corporation electrical engineer, and to Mr. W. H. Collis, the engineer-in-charge of the tramway department, for the courtesy extended to us during our visit to the tramway system and for the information they have kindly placed at our disposal. We are also indebted for much of the information to the contractors who have carried out the work.

GLASGOW CORPORATION ELECTRIC TRAMWAYS.

The development of electric traction at Glasgow has, broadly speaking, followed the same lines as that at Liverpool, a description of the tramways at which place is given in the preceding article. But there is this difference between the two, that whereas at Liverpool electric traction was decided on almost simultaneously with the taking over of the tramways by the Corporation from the original Company, at Glasgow the system has been worked for a considerable time by horses since the acquisition of the lines by the Corporation in 1894. The enormous advantages of electric traction over every other system of tramway operation could not, however, for long remain unheeded by so progressive a body as the Glasgow municipality, and although they have shown great hesitation in the adoption of the overhead system, the fact that they are desirous of giving electric traction a trial is proved by the short experimental line which was recently equipped on the trolley system between Glasgow city and the district of Springburn, and which, as refuted on p. 88 of our last issue, has already given the greatest satisfaction. The decision to make this experiment was the result of a visit of a sub-committee, together with the tramway engineer and general manager, to the Continent and America; and we may add that the equipment of the power station and line has been carried out under the supervision of the Corporation officials.



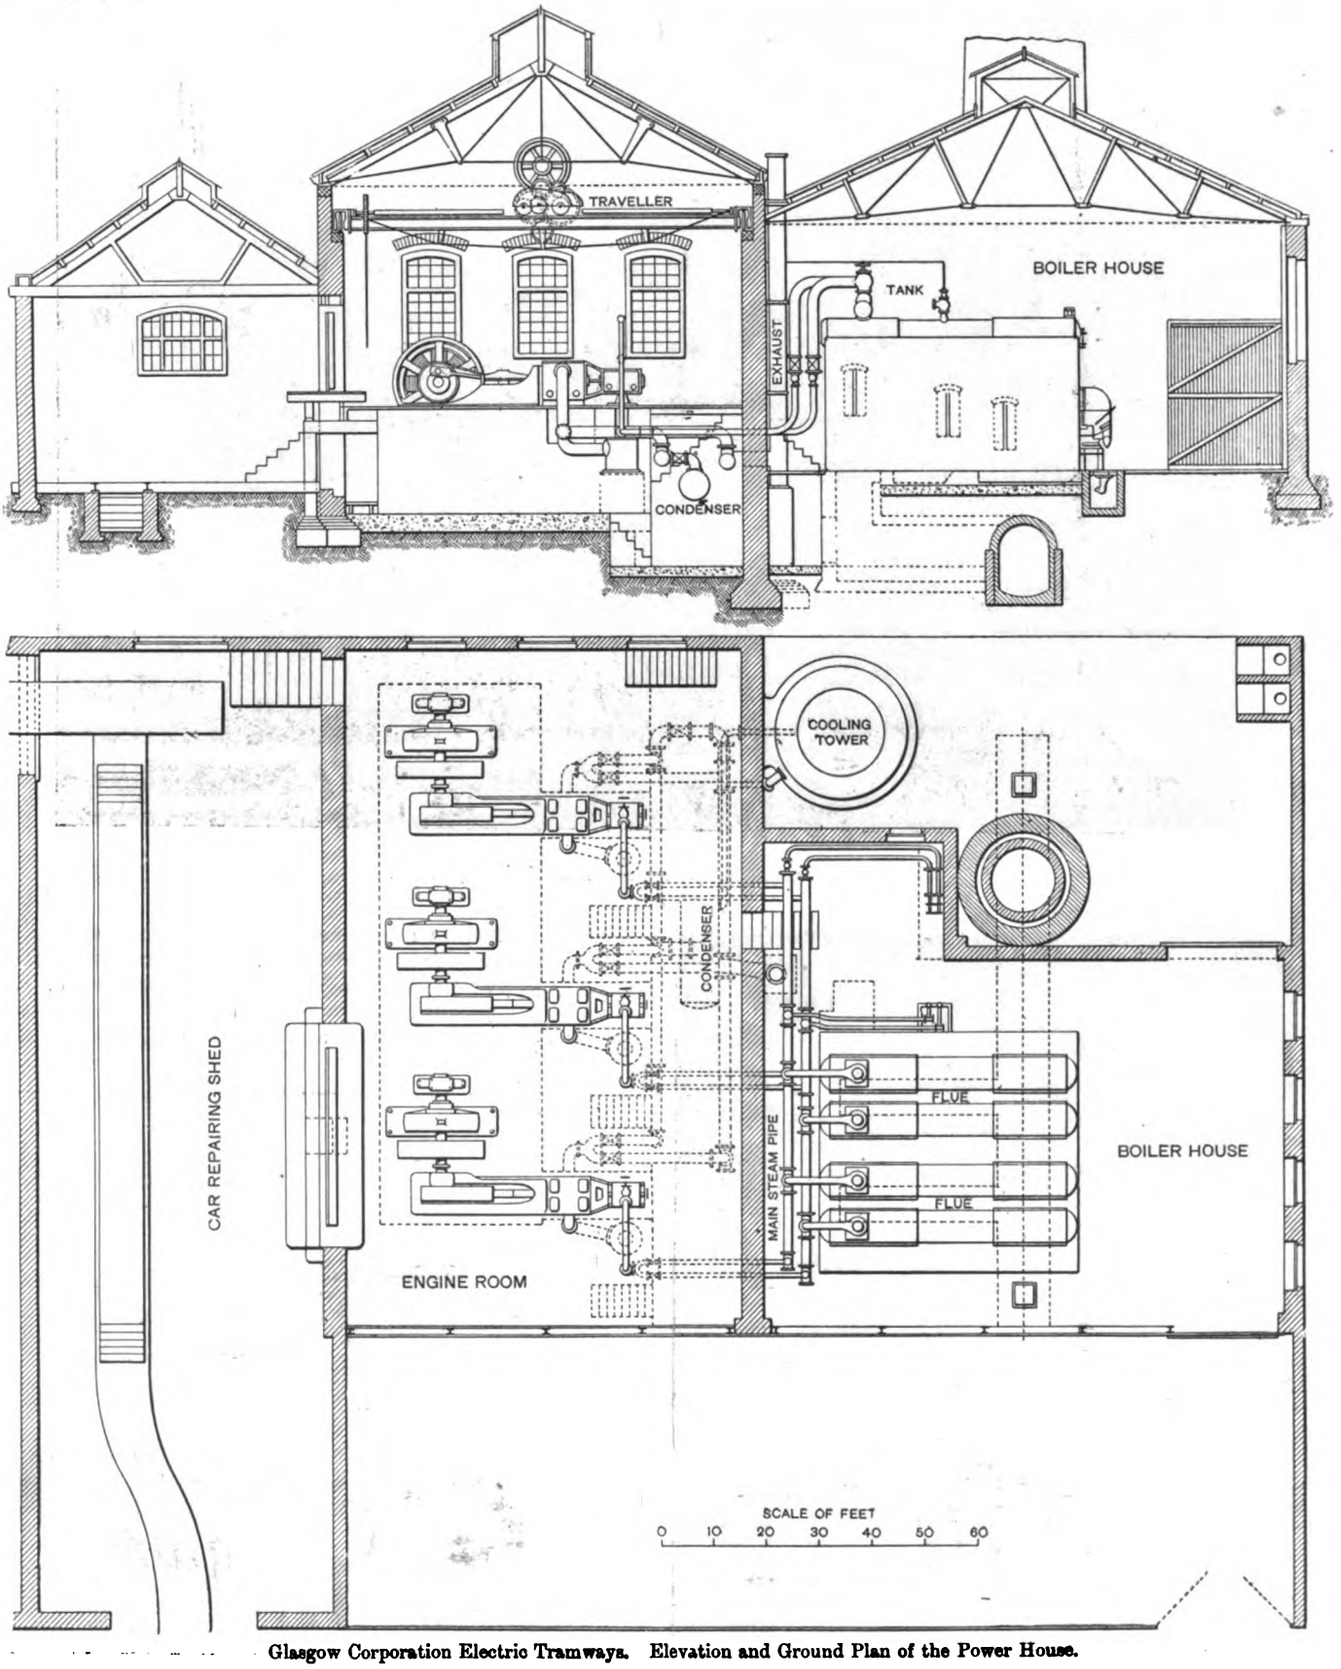
Map showing Glasgow Corporation Electric Tramways and Power Station.

Although representing only a very small fraction of the total tramway system of Glasgow, the electric line, a map of which accompanies this article, serves admirably for the purpose of an experimental trial of the overhead trolley system. It has been equipped both on the span-wire and centre-pole double-track system, but chiefly on the former, and the whole of the electrical overhead construction has been carried out by Messrs. Robert Blackwell and Co. The track has been relaid with 100lb. steel girder rails, bonded at the fish plates with double Daniel bonds of No. 00 B. and S. gauge. The rails, which are also cross-bonded at frequent intervals, are laid on a 4ft. 7½in. gauge of cement concrete. They were rolled by the Barrow Hæmatite Iron and Steel Co., in 45ft. lengths, somewhat over the usual length. The span wires are carried partly on side poles and partly on wall rosettes of an artistic design. The poles are built up of three sections of parallel steel pipe, and are principally 30ft. in length, but some of heavier type are 31ft. in length. When tested in position they are found to comply with a specified strain, viz., for the lighter type 1,000lb. strain at the top, with the pole sunk 6ft. 6in. in the ground, producing a temporary deflection of not more than 6in., and a strain of 160lb. producing a deflection of only ½in. With the heavy pole strains of 1,200lb. and 260lb. respectively produced these deflections. We may say that the poles were made by Messrs. Morris, Tasker and Co., and the rest of the overhead construction by Messrs. Macartney, McElroy and Co., under the contractors, Messrs. Robert Blackwell and Co. As at Liverpool, the trolley wires, where brackets are used, are carried on fiddle-string supports, instead of, as is commonly used in America, the rigid insulating support. It is found that the first-named gives a much easier passage to the trolley wheel under the support, and prevents the fracture of the wire at this critical point. The trolley wires are of

Digitized by Google

No. 00 B. and S. hard-drawn copper wire having a breaking strain of 6,000lb. They are duplicate throughout, and are supported by the usual type of strain insulators. The line is divided into half-mile sections, a section box being placed at each sub-division. These boxes are of cast iron, copper is half a square inch to each feeder, and cables are provided both for supply and return.

The rolling stock for this line is principally of American type, consisting of double bogey cars with centre and end entrances, besides a few shorter cars on rigid trucks. Some of



Glasgow Corporation Electric Tramways. Elevation and Ground Plan of the Power House.

and provide a switch connection with the feeders. There is also in each section box a telephone outfit and a set of lightning arresters. The feeder cables were manufactured by Messrs. Siemens Bros. and Co., and are buried. The section of the cars have been equipped by the Westinghouse Electric Co., and in other cases the cars are equipped with British Thomson-Houston plant. The motors, of which there are two in each motor car, are rated at 35 H.P., and are con-

Digitized by Google

trolled on the series-parallel system. A special arrangement has been introduced for the car lighting, a diagram of which is shown in an accompanying illustration. This arrangement provides for two circuits for the lamps in each car, there being two three-way switches so connected up that either head light can be put on to either circuit according to the direction the car is going. The switches for the lighting circuit are worked from one handle, and are so locked that the same lamp cannot be put on to both circuits at the same time. The motors are of the well-known enclosed railway pattern and call for little comment. The armature is of the drum type, and the fields are, of course, series wound. The motors are geared to the axles by single reduction spur gearing, the gear wheels being wide faced and of ample size to stand the heavy strains of tramway service. The motor gears are enclosed in an oil-tight casing, and the lower teeth of the spur wheel dip into a bath of oil. It will be of interest to our

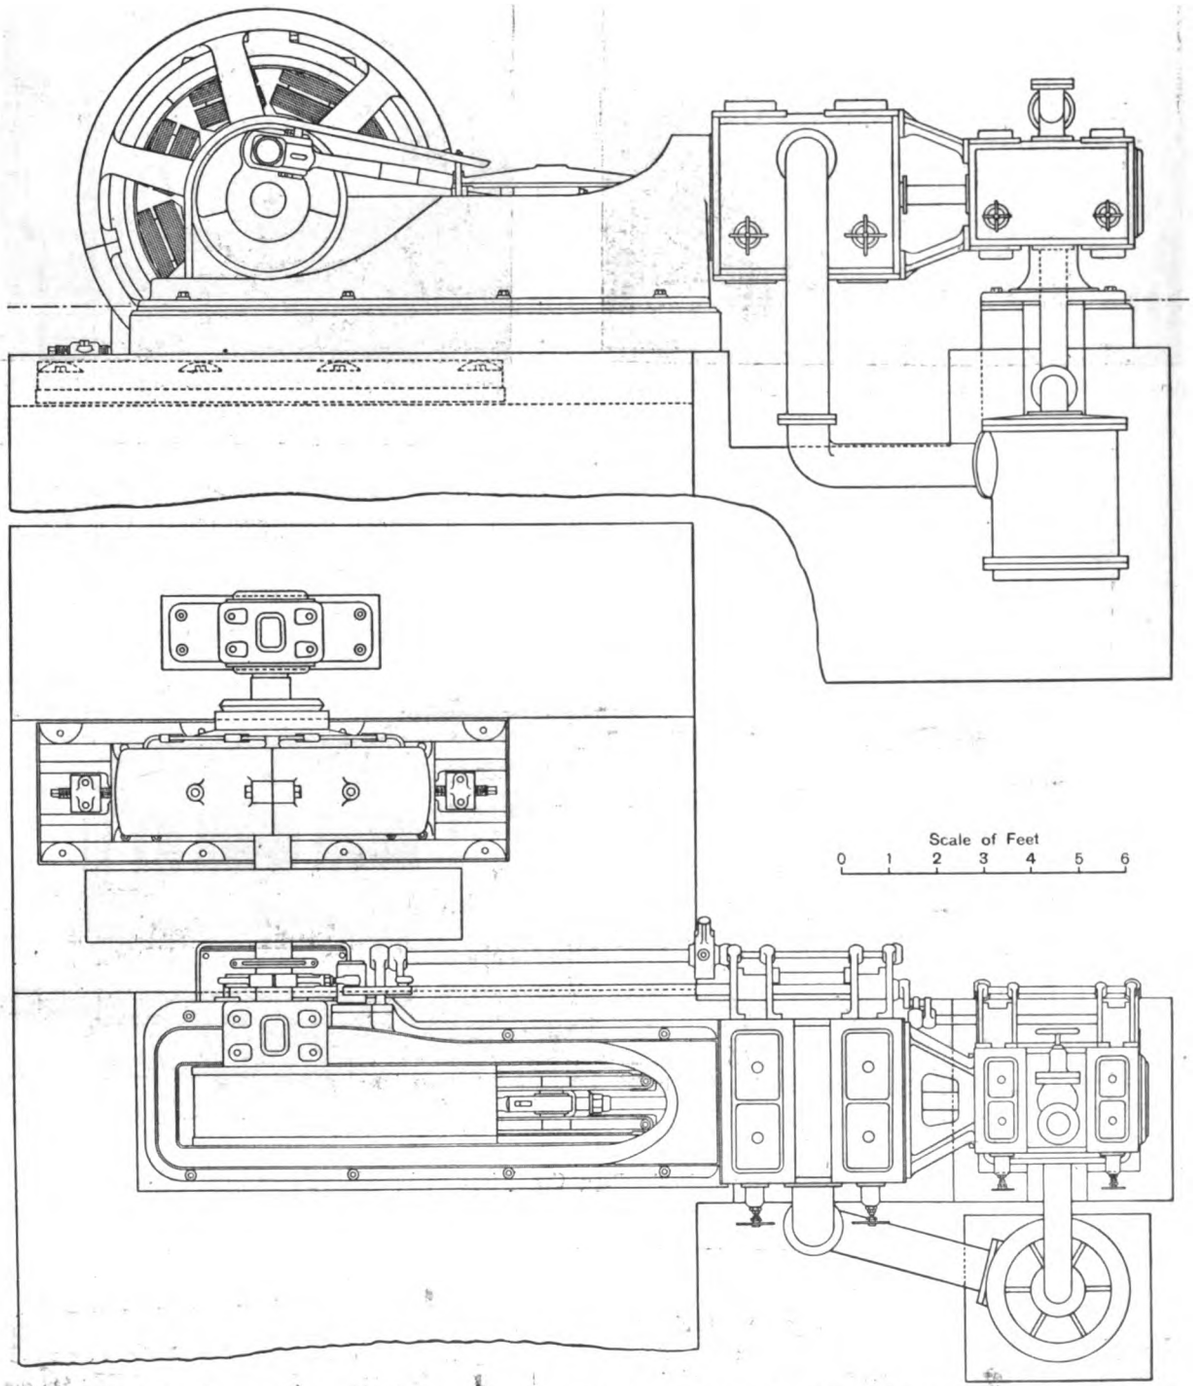
readers to know that the cars, although of American pattern, have been built at the Corporation shops in Glasgow, to the designs of Mr. John Young, the general manager. They differ in many respects from the Liverpool bogey cars, especially in not being provided with maximum traction trucks, all the bogey wheels being of the same diameter. The rolling stock consists at present of 21 single-deck American cars, two double-deck American cars, and two double-deck English type of car on rigid trucks. We understand that a series of very interesting and important experiments on electric brakes is being carried out on the cars by the British Thomson-Houston Co. These will no doubt go far to obviate the risk of accidents from brake failure.

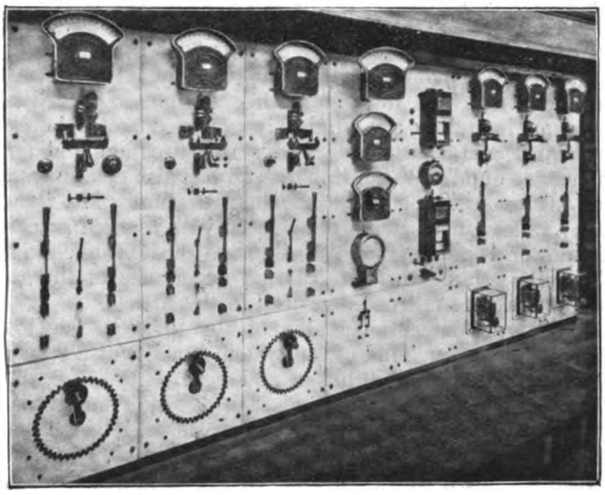
The power station for this tramway is independent of the electric supply power station worked by the Corporation, and is situated about half a mile from the Springburn terminus of the line. The dimensions and equipment of the station are shown in the accompanying scale drawings. Steam is generated by a battery of two Babcock-Wilcox water-tube boilers connected to independent duplicate steam main ranges, each of which feeds the standpipe of each of three direct-coupled steam-dynamo sets. The boiler-house equipment includes two steam feed pumps by the Blake and Knowles Steam Pump Works, Ltd. These are of the well-known Blake-Knowles horizontal duplex type. The boilers are stoked by Vicars' automatic coking stokers. The dynamo sets are driven by MacIntosh and Seymour horizontal compound tandem engines working condensing, supplied by Messrs. R. Blackwell and Co., the engines being direct-coupled to Westinghouse multi-polar generators. The sets run at 200 revolutions per minute, and have a rated capacity of 200 kilowatts, viz., 380 amperes at 550 volts. The engines have a 2ft. stroke, with cylinders of 11in. and 22in. diameter, and they are provided with exceptionally heavy flywheels and automatic expansion valves on both cylinders. To the exhaust mains are fitted two Blake-Knowles automatic exhaust relief valves. The condensers for the steam plant are of the Worthington type, the condenser water circulating through a large cooling tower, the air draught for which is produced by an 84in. fan driven by a Brotherhood steam engine of 10 H.P.



Glasgow Electric Tramways. Direct-coupled Westinghouse Multipolar Railway Generator and McIntosh and Seymour Steam Engine.

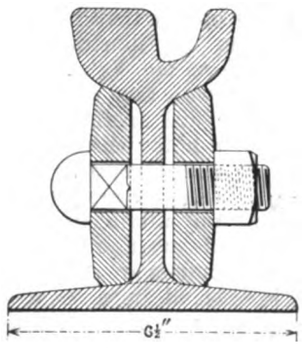
Digitized by Google

The generators are of the Westinghouse eight-pole railway type, consisting of a circular yoke, carrying inwardly-projecting pole-pieces of laminated soft steel, with field castings divided vertically and set up end-wise upon an independent bed-plate. The vertical position of the field affords excellent facilities for immediate inspection or removal of the armature or field coils without the necessity of removing the outside bearing or dismantling the engine. The generators are over-compounded for 10 per cent. drop at full load. The shunt and series coils are separately wound and are removable independently. The series coils are of forged copper conductors of rectangular



Glasgow Electric Tramway Power Station. View of Switchboard.

section. The armature core consists of punched discs of annealed steel, held together by cast-steel end plates, securely bolted in place. This core is carried on a spider pressed and keyed upon the engine shaft. Ventilating spaces through the spider and armature core are arranged so as to allow of a constant circulation of air through the commutator and wind-

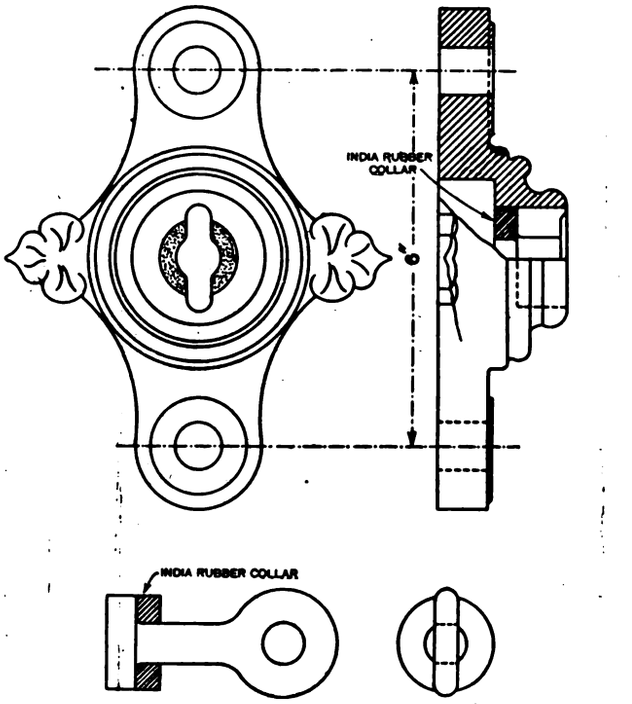


Section of Rail Joint on Glasgow Electric Tramway.

ings when the machine is running. The armature windings are carried in slots, and are made from bars of drawn copper, forged into shape on cast-iron formers. When shaped the bars are insulated with mica and fuller-board, and are baked to remove moisture. The coils are held in the slots by means of wedges of hard fibre driven into the armature near the end of the slots. The commutator consists of hard-rolled copper, the segments being insulated by mica. The brush holder mechanism is carried by brackets projecting from a ring concentric with and supported by the field. A hand worm engaging with the gear on the rim of this ring works the adjustment of all the brushes simultaneously.

The switchboard is also of the Westinghouse standard railway pattern, and consists of marble panels built into a framework of timber in one of the main walls of the building. It consists of eight panels, three of which are feeder panels, two Board of Trade panels, and the remaining three panels for the three generator sets. Inspection of the switchboard is provided by means of a gallery running behind it.

A very rapid service of cars is being run on these tramways, viz., a 2½ minutes headway for the entire route. The British public is not yet accustomed, either in Glasgow or in Liverpool, or in fact in any of the cities provided with electric traction, to the high speeds commonly met with in America; but, notwithstanding this, the round trip is made in very much less



Span-wire Wall Rosette designed by Messrs. Robert Blackwell and Co.

time than originally with horse cars. When the public is educated up to the maximum speed at which trolley cars can safely be run, the advantages of electric traction will be still more apparent than they are now. It is stated that the speed at Glasgow averages seven miles per hour, so that the entire journey of 2½ miles occupies about 21 minutes. The fare for the entire single journey is 1½d., and there are four ½d. section fares.

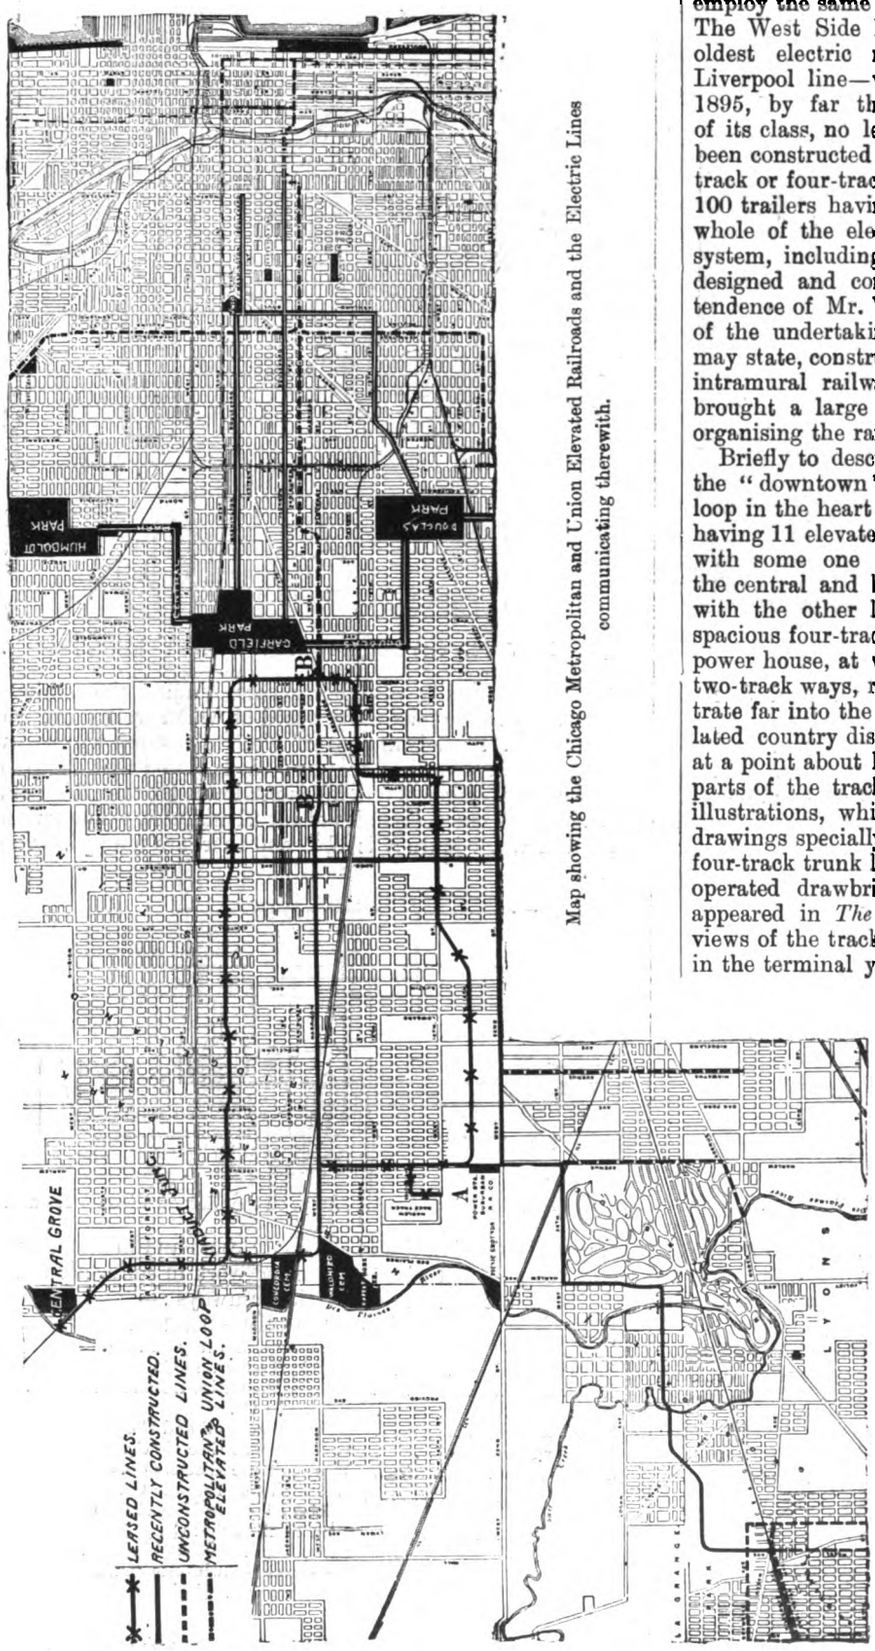
CHICAGO METROPOLITAN WEST SIDE ELEVATED ELECTRIC RAILROAD.

The Metropolitan West Side elevated railroad of Chicago was projected as far back as 1892, but was originally intended to be operated by steam. The success of the intramural electric line built for service during the Chicago Exhibition, however, encouraged the promoters to adopt electric traction, which has proved an uniform and pronounced success. Were there wanting anything to support this claim, apart from the operation of the line itself, such might be found in the conversion of all the Chicago steam elevated lines to electric traction on an identical system, and in the recent decision to employ the same system on the New York elevated railroads. The West Side line, or system of lines, although not the oldest electric railroad—having been ante-dated by the Liverpool line—was, at the time of its opening in April, 1895, by far the most important and extensive example of its class, no less than 18 miles of overhead road having been constructed at that date, all of which was either two-track or four-track way, and no less than 55 motor cars and 100 trailers having been at that time put into service. The whole of the electrical and other engineering work of this system, including the admirably-equipped power house, was designed and constructed under the direction and superintendence of Mr. W. E. Baker, who has also acted as manager of the undertaking since the inauguration. Mr. Baker, we may state, constructed and operated with marked success, the intramural railway at the Chicago Exhibition, and thus brought a large measure of ripe experience to the work of organising the railroad described in this article.



Map showing the Chicago Metropolitan and Union Elevated Railroads and the Electric Lines communicating therewith.

Briefly to describe the plan of the lines, we may say that the "downtown" end of the system consists of a rectangular loop in the heart of Chicago and near to the lake, this loop having 11 elevated stations, at each of which junction is made with some one or other elevated line. The loop encircles the central and busiest blocks in Chicago, and is connected with the other lines of the "West Side Elevated" by a spacious four-track way extending westward, or inland, to the power house, at which point it makes a junction with three two-track ways, radiating south, north and west. These penetrate far into the suburbs and beyond into the sparsely-populated country districts, the north-going branch being forked at a point about half way along its length. Views of various parts of the track are shown in some of the accompanying illustrations, which have been made from photographs and drawings specially prepared for us by Mr. W. E. Baker. The four-track trunk line crosses the Chicago river by electrically-operated drawbridges, an illustrated description of which appeared in *The Electrician*, Vol. XL., p. 233. One of the views of the track shows details of the third-rail construction in the terminal yards, and another shows a cross-over track running entirely through the yard, and still permitting the contact rail to be used for every movement without in any way altering its position. In one of these views the inspection sheds, where the motors are carefully inspected, and where small repairs are effected is shown. Each motor truck is inspected on an average once every three days. The intermediate stations on this line are very much of the same type as the specimen shown in one of the views. The terminal city station, however, is a more extensive structure.

As already stated, the power house is situated some distance from the terminus. It has been erected on a plot of land lying between the up and down tracks of the four-track way, and two of the tracks pass over the boiler house, as shown in the view of the exterior. This is one of the most compact, and, at the same time, admirably equipped stations we have ever seen. Its total capacity is 7,400 H.P., and there are four vertical compound engines, each coupled direct to multipolar railway generators. Two of the sets are rated at 2,500 H.P., and the other two at 1,200 H.P. each, the large generators having 12 poles, and the smaller ones only 10 poles. The engines are of the condensing type, water from the Chicago

Digitized by Google

river being brought through a special tunnel to the power station, and returning through another tunnel, the distance from the river being considerably over one mile,* diameter, weighing 70 tons in the case of the larger engines, while on the smaller engines the fly-wheels are only 18ft. diameter, and weigh 45 tons. The speed of the larger sets is

provided for each engine. All four engines were built by Messrs. E. P. Allis and Co., and are of their well-known railway type.

The boiler house is equipped with Babcock-Wilcox boilers, of the type well known in this country, and has a capacity of 7,200 H.P. in 12 boilers. The boilers are automatically stoked with chain-driven mechanical stokers of the Babcock-Wilcox type, the stokers being operated by two small oscillating steam engines, placed one at each end of the stoker's shaft. The coal is delivered to bunkers overhead, and is fed automatically to the stoker hoppers. The boiler furnace draught is produced by a chimney 150ft. in height and 12ft. 6in. internal diameter; also by two large Sturtevant centrifugal fans. In the boiler house there are two 1,000 H.P. Berriman feed water heaters, and two compound duplex boiler feed pumps manufactured by the Deane Steam Pump Co., of Massachusetts.

The track construction consists of 90lb. high grade T steel rail spiked to cross ties, the rails being electrically bonded near its centre to the supporting structure, which is also of steel. The third rail consists of 45lb. inverted channel iron elevated slightly above the timber safety guards, so as to provide certain contact with the car shoes. The third rail is insulated at intervals of about 5ft. on square blocks of pine saturated with paraffin wax, the blocks resting on iron pedestals uninsulated other than by the paraffin wax. Differing from the construction of the Liverpool Overhead Railway, the third rail of this, as, indeed, on all American elevated railroads, is carried at the side of the track either on one side

or the other according to the position of the points, switches, &c. For mechanical support the third rail is jointed by light fish-plates, and it is electrically bonded on the under side by three short copper strips.

The trains are built up of the American type of cars, one motor car hauling one or two trailers. Each motor car is 40ft. in length, and has a seating capacity of 40 passengers. It is equipped with two cabs, one on either end of the car, and in one of these there is a 3 H.P. motor for operating the air-pump for controlling the brake. The car is carried on two independent bogeys, and each bogey truck carries a 100 H.P. motor of the G.E. 2,000 type—*i.e.*, having a tractive force of 2,000lb. The motors are worked on the series parallel system. The collecting shoe for taking current from the third-rail slides at the side of the car on stiff springs, so as to ensure a good contact. On crossings the front shoe makes contact before the rear shoe breaks it, and this ensures continuity of power. Owing to the third rail shifting from one side to the other, the cars are, of course, equipped with shoes on both sides. The weight of the motor car, exclusive of the electrical apparatus, exceeds 20 tons. The trail cars are similar in construction, but of somewhat lighter build, and are not, of course, provided with cabins.

In conclusion, we have to acknowledge our indebtedness and express our thanks to Mr. W. E. Baker for the information he has placed at our disposal for the compilation of the above description of the railway.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Standard High Resistances.—There are at present two principal forms of high resistance in use: that made of insulated wire, which is reliable but costly, and the carbon line on ebonite, which is neither. F. B. Fawcett describes a method of constructing high resistances, which are both cheap and reliable. It is based upon the properties of the deposit from a cathode of gold or platinum on a glass surface in its neighbourhood. By making the cathode in the form of a grid of several wires stretched parallel to one another, and in the same plane an even deposit of the metal is obtained. The author twists gold and platinum wires tightly together, and thus obtains the deposit as an alloy. When a film is freshly deposited its resistance alters at a rapidly decreasing rate, the alteration continuing for many months. It is probably due to dissolved gas and to molecular rearrangement. It may be artificially matured by boiling the film for several hours under reduced pressure in a non-conducting and chemically inactive oil. If after this the film is kept in its oil bath its resistance undergoes no perceptible change for seven months, at all events. The resistance may be adjusted to any desired value by scratching gaps half way across it from both edges alternately. The capacity and inductance are negligible, and the temperature coefficient is very small, and may be made to vanish by suitably choosing the thickness.

[Fawcett, *Phil. Mag.*, November, 1898.]

Measurement of Electric Quantity.—R. Blondlot gives a method of measuring a quantity of electricity direct in electromagnetic units, and describes an electric meter based upon it. A long coil is laid down so that its axis is horizontal. In its centre is suspended another coil in the form of a ring, movable about a vertical axis. Both coils are traversed by the same current. The earth's magnetism being compensated, the ring assumes a position parallel to the turns of the coil. When displaced from that position, the ring oscillates, say, with period T. The moment of the couple exerted upon the ring is proportional to i^2, the square of the current. Hence the product i T is constant, and is nothing else but the quantity of electricity passing any cross section of the wire during the period of one oscillation. In other words, whatever the current strength, the quantity passing during one oscillation remains the same. Hence the total quantity may be obtained by counting the oscillations. To reduce to absolute measure the formula—

$$iT = \sqrt{\frac{K\pi}{ns}}$$

is used, where n is the number of turns of the fixed coil per centimetre of its length, s the area of the ring, and K its movement of inertia. The meter consists of an electro-magnetic arrangement, in which the ring only makes excursions in one direction, and an arm attached to it breaks the magnetising current on its return. The apparatus follows any sudden variations of the current strength with the greatest promptitude.

[Blondlot, *Journ. de Phys.*, October, 1898.]

Magneto-Optic Effects.—Henri Becquerel has repeated the interesting experiments of Macaluso and Corbino (see *The Electrician*, Nov. 4, p. 45). His verdict is that these new experiments present the greatest interest, inasmuch as they show, in a particularly sensitive manner, the profound disturbances of the propagation of light which are due to the proper motions of transparent media, when the latter vibrate nearly in unison with the luminous waves traversing them. With proper regulation of the breadth of the flame and the quantity of sodium in it, a number of bands can be obtained in fixed positions. The most striking form of the experiment is obtained when the nicols are crossed at right angles. When no magnetic field is present, the field is dark, and the D lines are feeble. On exciting the field, two very bright bands appear on each side of the two D lines, in place of the dark bands obtained with parallel nicols. These bright bands represent the radiation whose plane of polarisation has been turned through 90deg. by the magnetic field. An important fact discovered by the author is that the distances of the bands from D_1 and D_2 respectively are notably different, the distances from D_1 being about three-quarters of those from D_2. This recalls a similar anomaly in the cases of reversal and the Zeeman effect. In conclusion, though the discovery of the Italian physicists might have been foreseen from Kundt's law that $dn/d\lambda$ rapidly increases near an absorption band, it illustrates one of the consequences of that law in a peculiarly elegant manner.

[Becquerel, *Comptes Rendus*, Oct. 31, 1898.]

Emissivity of Platinum.—J. E. Petavel has added an important contribution to the already large literature on the heat given out by a platinum surface at high temperatures. The radiator used was a wire, and the author found that a thick wire had to be used for the double purpose of radiator and thermometer, even at the cost of a slight loss of sensitiveness, owing to the facts that in a thin wire maintained at a temperature above 1,200deg. the resistance increases rapidly with the temperature, the emissivity varies largely with the diameter, and convection currents have a strongly marked effect. The author used a platinum wire 0·112cm. in diameter, mounted in the axis of a glass, gun-metal, or iron cylinder 3cm. in diameter and 30cm. long, surrounded by a water bath. The numerous results obtained by the author are recorded in tables and curves. The first set of the latter shows the emissivities of the platinum wire in hydrogen and in air respectively, at various pressures. The emissivity is highest in hydrogen at 228cm., and decreases as the pressure is diminished. In dry air the emissivity is considerably less. In every case the emissivity rises with the temperature, of course, but whereas the curve of increase is approximately a straight line in hydrogen, it shows an acceleration at the higher temperatures in air, carbon dioxide and steam. To quote a few figures, the emissivities at atmospheric pressure and 1,000°C. in absolute C.G.S. units are: In dry hydrogen 0·0053, in dry air 0·0021, in air saturated with moisture 0·0021 (no difference), in carbon dioxide the same, in steam 0·0024. The author examined the formulæ of Stefan, Dulong and Petit, Rosetti and Weber for radiation at various temperatures, but found only the last to be approximately true between 400deg. and 800deg. For the intrinsic candle-power b per sq. cm. of glowing platinum at temperature $t°$ he finds the important formula $(t - 400) = 889 \cdot 6 \sqrt[6.9]{b}$.

THE THEORY OF THE ROTARY TRANSFORMER.

BY GISBERT KAPP.

(COMMUNICATED BY LLEWELYN B. ATKINSON, A.M.I.C.E.)

In the *Elektrotechnische Zeitschrift* of September 15th and the following numbers, Mr. G. Kapp has made an interesting contribution to the theory of rotary transformers, and the growing importance of this class of apparatus suggests that a *resumé* of this will be of interest to English readers. Mr. Kapp himself points out that, after all the controversy on continuous *v.* alternating currents, the present move, undoubtedly somewhat dominated by the necessities of railways and tramways, is in the direction of generation at the most suitable site, transmission by high-pressure alternating currents, and transformation to continuous current at a pressure suitable to the consumer. This contention he supports by the instance of New York, where one great central station is being established to supply all the existing stations, which will merely become transformer stations from which the supply is distributed. He also instances the Dublin tramways, where part of the line is fed direct from the generating station and part by current generated by three-phase alternators, transmitted and transformed by rotary transformers to continuous current at intermediate points on the line. The same system is being adopted for the Central London Railway.

The current may be generated by alternators of one or more phases, and two methods of transformation to continuous current may be adopted. The first is by means of a motor generator, with synchronous or non-synchronous alternating motor coupled by direct shaft connection or by belt to a continuous-current generator. A modification of this method is where the two windings are on the same armature in the same field, machines of this description having been built by the present writer so long ago as 1888; or, lastly, rotary transformers, in which an armature revolving in a field receives

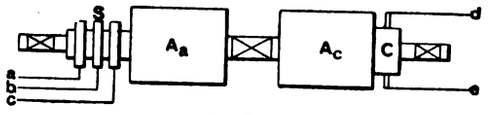

FIG. 1.

alternating current and emits continuous current from one and the same winding, a type of machine which, so far as the writer recollects, was first exhibited by Schukert at the Frankfort Exhibition of 1890.

The first arrangement is shown diagramatically (the magnet system being omitted) in Fig. 1, where a two or three-phase synchronous motor is coupled to a continuous-current generator. A_a is the alternating motor armature supplied from the line wires *a b c* through slip rings S; A_c is the continuous-current armature giving current from the commutator C to the lines *d e*. This arrangement has advantages. The pressure of supply and the strength of the field system of A_a, and thereby the phase relation between the supplying E.M.F. and current can be varied independently of the strength of the field system of A_c. But the loss of power is that due to the sum of the separate frictional and electrical losses of both machines, so that the net efficiency will not exceed, say, 92 per cent. by 92 per cent., or 85 per cent. The second arrangement, viz., that of two windings on one armature, has structural difficulties; it precludes independent field regulation, and is only a little more efficient than the foregoing. It is, however, better so far as armature reaction is concerned, particularly with multiphase currents. The third solution precludes independent field regulation, but has an enormous advantage in efficiency. The general considerations which lead to this result may be thus indicated. The alternating supply is led to certain points on the armature through slip rings, whilst the continuous current is taken off from a commutator; it therefore follows that twice in each revolution the point on the winding where the alternating current enters is in direct connection with the brushes, and at this point the current, or rather part of it, passes directly to the continuous current circuit, so that only during a portion of the revolution is the whole current traversing the windings of the armature. The object of Mr. Kapp's investigation is to show what is the relation between the normal output of a machine as a mechanically-driven generator and the output of the same machine as a rotary converter, the heating remaining the same. He also investigates the relation between the pressure of the continuous current generated and the pressure of the alternating supply.

We now follow Mr. Kapp:—

The E.M.F. of a continuous current armature with continuous winding rotating in a field of $2p$ poles is given by the equation

$$e_c = pNz\frac{R}{60}10^{-8},$$

where z is the number of effective windings, N the field strength, and R the revolutions per minute.

If the frequency $\sim = p\frac{R}{60}$,

we also have $e_c = \sim Nz10^{-8}$.

In the case of a single-phase armature the points on the armature at the intervals 0, 2π, 4π, &c., are connected to one slip ring, those at intervals π, 3π, 5π, &c., to a second slip ring.

In the case of a two-phase armature a further pair of slip rings are provided connected to the points $\frac{\pi}{2}\ \frac{5\pi}{2}\ \frac{9\pi}{2}$, &c., and the points $\frac{3\pi}{2}\ \frac{7\pi}{2}\ \frac{11\pi}{2}$, &c., and the pressure per phase is in each case given by the number of windings lying within the interval π.

We have, therefore, in the case of the alternator side, to take for z half the value before named, and the equation for the alternating E.M.F. stands

$$e_a = K \sim N\frac{z}{2}10^{-8},$$

where K is a coefficient which depends on the constructive data of the machine, so that

$$\frac{e_a}{e_c} = \frac{K}{2}.$$

The two-phase armature has four independent leading wires, that is the wires a_1 a_2 for the phase a and the wires b_1 b_2 for the phase b. The pressure between a_1 and a_2 or between b_1 b_2 is called the phase pressure. Such an armature can, however, be worked also at a four-phase armature, in which case the pressure is that between two points separated by points $0\ \frac{\pi}{2}$ or $\frac{\pi}{2}$ and π that is between a_1 b_1 or b_1 a_2 being a resultant pressure. The resultant pressure is $\frac{1}{\sqrt{2}}$ of the phase pressure, and the relation between the resultant pressure and the direct current pressure is given by the equation

$$\frac{e_a}{e_c} = \frac{K}{2\sqrt{2}}.$$

For a three-phase armature the leading in points are at intervals $0\ \frac{2}{3}\pi$, $\frac{4}{3}\pi$, &c., and as only a mesh coupling is possible the resultant pressure must be the phase pressure. For the alternating current side of such an armature in place of z must be used $\frac{1}{3}z$, and the coil width is $\frac{2}{3}$ of that first taken. We therefore have

$$e_a = K \sim N\frac{z}{3}10^{-8},$$

$$\frac{e_a}{e_c} = \frac{K}{3}$$

If now we take the values of K corresponding to the pole widths comprised between $\frac{2}{3}$ and $\frac{1}{2}$ of polar pitch (v) we can set out the following table for the values of the alternating E.M.F. in terms of the continuous current E.M.F.:—

$\frac{P}{v}=$		Current system.
$\frac{2}{3}$	$\frac{1}{2}$	
75 per cent.	82 per cent.	Single phase.
75 „	82 „	Two phase.
65 „	71 „	Three phase.
53 „	58 „	Four phase.
37 „	42 „	Six phase.

Digitized by Google

For the three, four, and six-phase systems, the percentages given refer to the resultant E.M.F. Loading the machine does not much alter the values. The alternating current is a motor current, the continuous current a generator current, and, in consequence, the armature reaction is only dependent on their difference. This is small, however, with moderate phase lag, and with no lag varies little. Another point tending in the same directien is the small internal pressure fall due to resistance in modern generators, so that for present purposes no further corrections are necessary.

A study of the table shows that in all cases the alternating pressure is less than that of the direct current, and since in most cases the continuous current is required not to exceed 100 volts, it becomes necessary to provide a transformer between the high pressure line and the rotary converter. Fig. 2 shews the arrangement for converting from three-phase high pressure to continuous moderate pressure current. A three-phase transformer receives current from the high-pressure lines *a*, *b*, *c*; A is the armature of the rotary, C the commutator S, the slip rings of the magnet system being omitted.

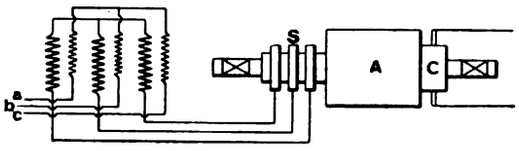

FIG. 2.

The relation of the output of such a rotary converter will next be considered, and in the course of the investigations it will be shown that whereas for single phase currents the output of a given machine is less than that of the same machine used as a belt-driven generator, for two, three and other phases the output is greater, the effect of current lag will also be discussed.

(*To be continued.*)

ELECTRICITY WORKS ACCOUNTS.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared :—

Oldham Municipal Electric Supply Works.

The Oldham undertaking, which commenced supply on March 20, 1894, stands in a high position among electrical supply concerns as regards costs of working. There are only about four stations of any output with lower costs per unit than Oldham for 1897-8, while for its output—viz., 322,000 units—it bears the lowest figure in this respect.

The authorised capital stands at £52,000, of which £46,650 has been received, borrowed at rates varying from 2⅝ per cent. to 3¼ per cent.; £2,000 (at 3 per cent.) has been repaid, and £49,060 expended at March 25th last, representing £75 per kilowatt of generating plant installed. During the year the extension of the station has been completed, and an additional boiler has been connected to the dust destructors of the Sanitary Committee. Another generating set of a capacity of 360 H.P. has also been put down, and contracts entered into for yet another boiler and two 360 H.P. generating sets. The expenditure during 1897-8 amounted to £3,777 to buildings, plant £3,675, and miscellaneous £79.

Consequent upon the addition of 50 consumers the equivalent lamp connection has risen from £15,763 to £21,626, or about 37 per cent., while the output has increased from 227,982 to 322,203 units sold, or more than 41 per cent. The average price obtained per unit has dropped in consequence of substantial reductions in the tariff.

Very satisfactory is the reduction noticeable in the total costs, viz., from 2·76d. per unit in 1896-7 to 1·79d. for last year. Works costs have been reduced by no less than 0·7d., and economies have also been effected in the management charges.

A working profit of £3,492 has been made, representing nearly 8 per cent. on the mean capital. Out of this and the balance from the previous year of £2,793, £2,793 has been carried to the depreciation fund, £905 towards the sinking fund, and £1,236 has been paid in interest on loans, leaving a balance for next year of £1,351.

Further reductions have been made in the price charged per unit; from March 25th last the rate is 4d. for the first two hours of average maximum demand, and 2d. after; while for street lighting the charge is 2½d.

Halifax Municipal Electric Supply Works.

The Halifax concern started electric supply in December, 1894; our tables, therefore embody analyses of the second and third completed years of working. The authorised capital amounts to £59,950; of this, £50,434 has been received (borrowed at rates from 2¾ per cent. to 3¼ per cent.), and £1,558 repaid. The capital expenditure to date is £57,783, representing £68 per kilowatt of generating plant. Included in this total is a sum of £2,389 on accumulators in view of supplying the tramways with energy. Seventy additional consumers and an equivalent of 6,654 8-c.p. lamps have been connected up to the supply during the year. The output in units sold shows an increase of 35 per cent., having reached 239,814, as compared with 177,531 in 1896-7.

Reductions in the price charged per unit has reduced the average price obtained from 5·86d. to 4·85d. A great improvement has been effected in the costs, the total cost per unit last year being 2·87d., as compared with 3·57d. Works costs have been reduced a halfpenny, and management and property charges nearly 0·2d.

The working profit for the year amounted to £1,975 or 3·77 per cent. of the mean capital. £1,846 has been carried to the sinking fund, and £1,471 paid as interest on loans, resulting in a deficit of £842, which, like that of the previous year, is met by a vote from the general district rate.

The following table is instructive as regards the progress of the Halifax undertaking since its inauguration :—

—	Quantity generated B.T.U.	Quantity sold.			Quantity used in works.	Number of public lamps.	Number of consumers.	No. of 8-c.p. lamps connected.	Revenue.	Expenditure.	Deficiency.
		Public lamps.	Private consumers	Total.							
March 31, 1895, four months ...	27,100	...	21,793	21,793	2,200	...	92	4,630	£571	£1,661	£1,090

The Electrician.

Oldest Electrical Journal (established as a weekly Journal 1861—1878).

ublished every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician' *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d	

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By B. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. **VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS.** New Edition. Price 12s. 6d., post free. **VOL. II.—THE UTILISATION OF INDUCED CURRENTS.** Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

THE SOCIAL INFLUENCE OF ELECTRIC POWER.

That the introduction of electric power into civilised life exerts a marked influence tending towards improvement in the social condition of the community must afford no little gratification to every member of the electrical profession with a soul for something beyond mere sordid gain. Engineers are not to be expected, any more than are other business men, to place this consideration in front of the prosaic desire to find bread and butter for themselves and those dependent upon them; but it is nevertheless pleasing to know that the general influence of their collective activities makes for something higher than profits and dividends. It is, perhaps, not recognised as often, nor emphasised as forcibly, as might justly be done, how much more than any other of the material forces that have elevated social life has electricity in all its varied applications wrought social and even moral good to mankind. That the influence of these forces is not purely material, but has a pronounced social and moral aspect, cannot be denied by anyone who choses to examine the facts; and it is tacitly implied by the dictum admitted by those in whose charge is more directly placed the spiritual and moral welfare of the people—the clergy—namely, that crime and social evil of every description are to an enormous extent fostered by the influence of the environment within which they abound. In the early days of electric lighting in public streets, it used to be said, we remember, that each arc lamp obviated the services of one policeman; but this is not the only direction in which the adoption of electricity has wrought the higher service of preventing, rather than *ex post facto* curing, the mischievous effects of an unhealthy environment. Again, while it may be admitted that material conditions largely influence social and moral welfare, some may be disposed to deny that, in this respect, electricity has done more than has been accomplished by other material forces, such, for example, as steam. The point is one which cannot be argued conclusively except at greater length than space can be devoted to now; but we would remark that, whereas in many respects the introduction of steam power has created in society conditions of living that are physically, socially and

Digitized by Google

morally unhealthy, this has never resulted in consequence of the introduction of electricity, in whatever manner applied. We do not, of course, imply that in the whole range of electrical engineering there is not one unhealthy industry; though these, be it noted, are in an extremely small minority. What we do insist is that, wherever electric power has been introduced as a material agent in social or industrial life, the tendency towards a better condition of living has been greatly accelerated thereby. Whether in its earlier application in the electric telegraph, or in the later and heavier forms of electrical engineering represented by electric lighting and power supply, and whether we contemplate its introduction into this country alone, or turn to the parts of the world where these latter applications have been more extensively fostered, electricity surely can lay claim to be the foremost of the civilising and socially-elevating physical forces at human command.

It is not, however, our purpose in this article to discuss in detail the social influences of every one of the numerous applications of electricity, but rather to deal only with two of them which are at the present time more prominently occupying the attention of the electrical profession; we refer to electric traction, and to the use of electric motors for industrial purposes. Electric traction, indeed, is fast assuming, if it has not already done so, the magnitude of a question of national importance. There is not a leading city and scarcely an important town in the United Kingdom the local authorities of which are not holding in serious consideration the advisability of sanctioning the introduction of electric tramway traction, or of introducing it themselves. Broadly speaking, these local authorities are divided into two classes: those which recognise that electric traction is better adapted than any other form of traction to meet the needs of the community, and who encourage its introduction; and those who, upon various pretexts, throw obstacles in its way. Upon this latter class a tremendous responsibility must rest, to which, we believe, they are scarcely alive; for if, as we hope to show, the social and moral welfare of important sections of the population of our cities and large towns can be vastly improved by the provision of electric tramway traction, how shall they be judged who blindly withhold this blessing from the community? Let us commence our argument by going to the core of the problem; and, for simplicity's sake, we will take one city—the largest in the world—by way of illustration. The argument can be applied to any other large city by merely changing the names. Fringing the south side of the Thames, between, say, Lambeth and Southwark, there is a belt of densely-populated districts, the majority of the inhabitants of which belong to the wage-earning class, and are unable to live elsewhere because their small earnings and long hours of work prevent them from spending daily the time and money that would be involved by living further from town. It will scarcely be credited that the density of population of many of these districts considerably exceeds one thousand individuals per acre. Beyond this belt of squalid humanity there lies another belt of suburban residences; and outside this, not more than five or six miles from the City, there commences a wide stretch of sparsely inhabited and but scantily used country. These are conditions repeated in innumerable large towns. They formerly occurred in many of the cities of Canada, the United States and on the Continent; but in those places the advent of the electric tramway wrought a complete change in the conditions of life of the class of people akin to those so unhealthily packed together in Walworth and the Old Kent-road. Rapid transit and cheap fares have enabled the artisan and the humble wage-earner to flee from the scene of squalid life, and to establish a healthy cottage home on the outskirts of the city where he works. No longer are the sons and daughters of toil obliged to herd together in barrack-like tenement buildings or dingy courts and alleys; for, with no more cost to themselves, and without cutting too much into their hours of recreation and rest, they find it possible to live six, or even ten, miles from their business. With horse tramways this, of course, is impossible, both on account of the time wasted and because of the high fare; but electric traction is not dangerous at much higher speeds than are possible with horses, and the low cost of operating electric tramways permits of very low fares being charged. In many American cities, for instance, the fare for a ten-mile journey is only the equivalent of our penny fare—taking into account the higher scale of American living—while the distance is covered in considerably less than an hour. We have no hesitation in asserting that electric traction, more than any other factor, has completely transformed the conditions of town life in the United States and in Canada, and the change has been one wholly tending towards social and moral elevation. There appears to us no valid reason why its introduction into this country, in places similar to the example we have cited from London life, should not produce equally beneficent results. On the contrary, the density of population of our large cities being now far in excess of what it ever has been in America, it would be reasonable to expect a proportionally greater amelioration. To remove from over-crowded areas a large proportion of the working class, and to place these people in rural homesteads, in a healthy atmosphere and close to the sources of wholesome and fresh food supply, is a task well befitting those responsible for the condition of the people. In the face of facts like these it undoubtedly behoves local authorities who have the welfare of dense masses of humanity in their charge to see to it without delay that efficient systems of electrically operated tramways are provided, so that this highly desirable process of decentralisation of the population may be brought about.

Apart from traction, the gradual adoption of electric power is working a change for the better in the social condition of the working classes, through the substitution of electric motors for other forms of engine power in mills and factories, &c. We do not believe that the provision of cheap electric power tends to scatter workmen from large factories to small home workshops, as has so often been asserted it would do. There are factors more important than the cost of power which decide between the factory system and the home-workshop system. But even in large mills and factories the change from the old method of running to the modern method of driving by electric motors is not without an elevating influence upon the character of the men which is not unobserved by those who have the opportunity to judge. The cleanliness of the electric motor itself, and the neatness, cleanliness and order which it renders possible in the workshop, in a way that no other motor can do, are in themselves potent, if simple, influences for social good. Men working in such surroundings are as surely elevated by their sweetness and light as they must be depressed and brutalised when obliged to do their daily work amidst grime and filth and in an atmosphere charged with unhealthy vapours.

The lesson which, in the foregoing reflections, we have principally sought to drive home, is that every encouragement should be given by Parliament and by local authorities generally for a well regulated and efficiently controlled supply of electric power, and for systems of electric tramways, throughout the United Kingdom. For, the advantages that will accrue therefrom to the nation count for much more than

Digitized by Google

the mere provision of motor-driven in place of horse-drawn tramcars, and motors in place of steam or gas engines in industrial works. Indeed, when regarded from the point of view of lasting national good, it will probably be conceded that the merely material advantages derivable from the introduction of electric power for these purposes are of less importance than the elevating influence they are known to exert upon the social and moral condition of the community.

REVIEWS.

Street Railway Roadbed. By MASON D. PRATT and C. A. ALDEN. (Street Railway Publishing Co., New York.) 1898.

This little work of 135 pages has been written by two engineers having a thoroughly practical knowledge of their subject, and this is the more welcome, as the problems connected with such work as the choice and laying of rails and the filling in of the roadway are almost entirely of a practical nature, and the merits and demerits of various systems and designs can only be determined by actual and continued experience. Most of the contents of the book apply as well to horse and cable as to electric traction, for the work confines itself to the discussion of rails, and their joints, switches, &c., and of the materials and methods employed for laying the track; though, of course, owing to the enormous extent to which electric traction is employed in the States, the authors have evidently had electrical working chiefly in mind. Still, from the electrical engineer's point of view, the work is somewhat disappointing from the very fact that its scope is so contracted. For instance, nothing is said of bonding between the rails; or of the methods of laying the bare or insulated feeders connected to the rails for the purpose of reducing the drop of voltage on the rail return; or of the construction of the culverts employed with slotted-conduit systems. Information on these subjects from authors who are acquainted with the best American practice would be of the very greatest value, and we hope to see before long a second work from the same writers dealing with them. Likewise something might be said concerning trolley poles and the foundations, &c., they require.

But enough as to sins of omission; it is pleasanter to dwell on the many positive virtues exhibited by the work. The first part, that dealing with the development of the design of the rails themselves, is particularly lucid and well written. There is in this connection a great difference between American and English practice. In the States it is common to give the rail what is called a "tram"; that is, a flat surface, perhaps 3in. wide, flush with the roadway, for the convenience of the ordinary vehicular traffic. Once on this tram a vehicle is easily kept there owing to the projecting head of the rail. This system bears very hard on the tramway company, as not only are the cars hindered by the traffic in front, but also the track between the rails, which the Company has to keep in repair, suffers from abnormal wear and tear. Yet in many cases the local authorities insist on the trams being adopted. With reference to rails it is interesting to note that, whereas with horse or cable cars the wear may not exceed $\frac{1}{4}$in. in five years, with electric cars running under the same conditions it will be but one year before the same amount of wear has taken place. This is partly due to the increased weight of the electric car and partly to the fact that its power is applied internally to axle. The wear when going up an incline may be double that on the parallel downward track. But space will not permit of even the mention of the many interesting facts noted in the particularly well written first half of the book.

The second half is, perhaps, not so complete and satisfactory as the first. For instance, no illustrations are given of switches and mates, though these are by no means the least important parts of the equipment of a track. Nevertheless the methods of laying-out the curves where the track passes round corners are well and fully dealt with. On the whole the work can be thoroughly recommended to those who have to deal practically with tramways or light railways.

Electrical Traction. By ERNEST WILSON. (London: Edward Arnold.) 1897.

It is with mixed feelings that we lay down this book. On the one hand the work is undeniably interesting so far as it contains numerous descriptions of work actually done and plant actually employed, taken for the most part from various technical journals. On the other hand, it bears throughout evidence of the hand that has had little or no practical experience of its subject matter. This shows itself not only in errors, or half errors, of statement, but also in that manifest lack of the sense of proportion and importance of things which above all marks off the mere writer from the man who has lived (and shall we say suffered?) amidst that which he describes. For instance, take the six pages devoted by the author – in a work of only 250 pages—to a full account of some comparatively trivial tests that he has himself happened to make with two out of the numerous types of storage cell. He gives the experiments, table after table, in full, and leaves us there without so much as an attempt to point out the merits of the cells or in any way to sum up the results. Perhaps had he done so he would have seen how unimportant these were, and have spared us.

As examples of the errors that the author makes we may refer to pp. 27 and 28, where the efficiency of motors when arranged in series and in parallel is discussed. Throughout the discussion it is assumed that the losses in eddy currents, hysteresis, friction and windage remain constant over very great variations of speed and output. Now those practically acquainted with dynamos and motors know that these losses (which are as important as the copper losses in the machine) vary enormously with speed and output, and that any calculations of efficiency based upon the assumption that the losses are constant are altogether misleading. Further, from the table on p. 22, and the remarks thereon, it would seem that the author is unaware that over seven years ago methods of ascertaining by direct experiment the way in which these losses vary were published. Again, a few pages further on (p. 24), we have additional evidence that the author is by no means at ease with his subject. A second collecting shoe, if required at all, is not required "to diminish the risk of breaking the shunt circuit," but to diminish the risk of breaking the main circuit, which might lead to the magnets losing their magnetism and an excessive current passing through the armature when the shoe again makes contact with the conductor. To take another random instance of the author's uncertainty, we may point out that, on page 190, he takes the voltage on the Dublin line as 3,000, though, on p. 188, he has just told us that the generators only give from 2,300 to 2,500 volts.

But, after all, the question is, for whom was the book written? to what class of reader was it intended to appeal? It must be admitted that it could not be intended for the traction expert, for its scope is manifestly elementary and too incomplete for such a purpose; nor for the student, for, though elementary and incomplete, it yet assumes considerable knowledge of the subject, particularly when anything at all difficult is being discussed; *a fortiori* it is far too technical for the popular reader. This almost well clears the field, and all that can be said is that it may prove agreeable reading for the engineer who, having a desire to know how an electric tramway is worked, but has no intention of going further into the matter.

The style in which the book is written is often unnecessarily obscure; and it is not without a shudder that we read such phrases as "when hot weather steps in," "magnetically speaking," or "motors deliver only 21 H.P. to the rails."

The Telephone. Outlines of the Development of Transmitters and Receivers. By WILLIAM J. HOPKINS. (New York: Longmans, Green and Co.)

This is a short treatise dealing merely with the construction of transmitters and receivers, and passing in review some of the principles underlying their design. All other pieces of apparatus used for telephoning are considered outside the scope of this book. Narrow as the subject is when confined within these limits, the author cannot be said to have done full justice to it, as the historical notes and descriptions of historical

Digitized by Google

forms of instruments are very scant, and, although the present American types of instruments are well described, no reference is made to some of the receivers and transmitters most used in this country and on the Continent of Europe. Notwithstanding, the author gives much matter that will be useful to the student of telephony, the most interesting, perhaps, being an account of the experimental investigations carried out by the Massachusetts Institute of Technology, under the direction of Prof. Cross, on the efficiency of different types of microphonic contacts, and the effect of different degrees of magnetisation of the permanent magnet in the receiver. This account would be more useful, however, if the curves had numerical scales marked on them. Before concluding this notice it is necessary to correct two somewhat misleading statements in the book. It is unfair to say that no patent was issued to Prof. Hughes for his microphone; no patent was applied for. The other statement is that the action of transmitters depending on magnetic induction "is not altogether simple, and is still somewhat in dispute." To quote further:—

> The operation of a magneto telephone has been variously attributed to one or more of these causes—(*a*) Molecular vibration of the iron core as in the Reis receiver. This undoubtedly exists, but is so weak that probably in most cases it would be impossible to detect it. (*b*) Variation in the attraction of the core for the mass of the diaphragm; (*c*) Action of the spirals of the core. It would be difficult to separate this last action from the general change in magnetic flow, and indeed no good reason appears why this separation should be attempted. The second cause named is by far the strongest, and in most cases probably the only observable action.

Although the principles of the Bell telephone may have been in dispute when Du Moncel published his famous treatise, it is acknowledged at the present day that the action of the magneto transmitter is simply that the motions of the diaphragm cause variations in the length of the air-gap of the magnetic circuit, which in their turn cause variations in the magnetic flux and consequently produce currents in the coil. This is both simple and, we believe, undisputed; in fact, the author gives the correct explanation in his chapter on "Magneto Instruments," but in the passage quoted he seems to be thinking of what takes place in the receiver while he is writing about the action of the transmitter.

The Indicator Handbook: a Practical Manual for Engineers. By CHARLES N. PICKWORTH. Part I. The Indicator: Its Construction and Application. (Manchester and London: Emmott and Co.) 1898.

It is not often we have occasion to review a handbook which so consistently bears out its title as the one under present notice. As is so necessary in a handbook, the information on any point within the scope of the subject is remarkably get-at-able, chiefly because from beginning to end the little volume is unburdened with redundant matter. In its eight chapters the author has usefully and logically dealt with the construction, the errors, and the practical manipulation of the indicator and indicator-reducing gears. Not only are steam-engine indicators referred to, but indicators for gas, oil and ammonia compression engines or machines, and, finally, mean pressure, double and hydraulic indicators. The only misprint or error we have come across throughout the work is what appears to be a wrong reference to a figure on page 53. The book bears the stamp of having been written from actual experience, and we can heartily recommend it as a reliable guide on the subject with which it deals.

The Comprehensive International Wire Table. Compiled by WILFRID S. BOULT, Assoc. M.Inst.C.E. (London: "The Electrician" Printing and Publishing Co.) 1898.

It is a lamentable fact that there are so many wire gauges in existence, there being at present no less than three in constant and frequent use, and others which are employed occasionally. While regretting that such a thing as a comparative table of wire gauges should be necessary, we are glad to have one in such a comprehensive form as Mr. Boult's, which has just been re-issued. Over 450 conductors of different sizes are tabulated in order of their sectional area, a column being devoted to each, in which data are given concerning diameter, section, weight, resistance, current capacity and heating, there being twenty or thirty items in each column. The table should be of especial value to those engineers who have frequently to deal with foreign specifications; and for all who experience difficulty in the work of conversion from one gauge to another.

Taschenbuch für Monteure Elektrischer Beleuchtungsanlagen. By S. FREH. V. GAISBERG. Sixteenth Edition. (Munich and Leipsic: R. Oldenbourg.) 1898.

Less than a year ago we reviewed the fourteenth edition of this useful pocket-book. The present edition includes several slight additions, but the previous size of the book has been retained by the omission of obsolete and redundant matter.

Kalender für Elektrochemiker sowie Technische Chemiker und Physiker. For 1899. Edited by Dr. A. NEUBURGER. (Berlin: M. Krayn)

Several additions have been made to this two-volume pocket-book, but the numerous inaccuracies referred to in our review of the first edition have not all been corrected.

AN ELECTRICALLY-OPERATED FOUNDRY.

An article in a recent number of the *Western Electrician*, of Chicago, describes an interesting installation of electric motors for the foundry of the Reading Car Wheel works, in Pennsylvania. We give the following particulars, which are abstracted from the article referred to:—The adoption of

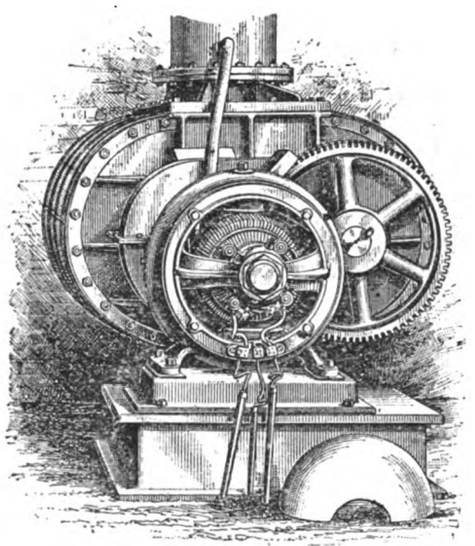

FIG. 1.—Electrically Operated Foundry.—Motor-driven Pressure Blower.

electricity for motive power was due to a belief that it would prove to be economical in cost and much more convenient than steam. The current is taken from the mains of the city lighting plant, and the service has so far been very satisfactory. The system covers all appliances which can be run by power, and is very complete. In Fig. 1 is shown a positive-pressure blower, with a special cast-iron sub-base and directly geared by a rawhide gear to a 85 H.P. motor.' In the illustration, the motor is shown with the casing removed, but when in operation the working parts of the motor are entirely covered up. Several times when the bottom of the cupola has been dropped, the motor has been spattered with molten iron, but no trouble has been experienced on that account. Fig. 2 shows the tumbling barrel, also directly connected to a back-geared motor, and used to separate the scrap iron and dirt coming from the cupola. In the cupola-charging room, which is directly over the testing room, are located the motors for driving the elevator and the drop for breaking old car wheels. These motors are equipped with regular reversing elevator controllers and are direct-connected to the elevator mechanisms. The elevator has a capacity of three tons and the break-drop has a weight of 2,000lb. and a fall of 40ft.

The casting and cleaning department has an area of 150ft. by 80ft. The moulds are arranged in rows or floors lengthwise of the building, each row or floor accommodating 20 moulds. There are ten floors, presenting a capacity of 200 car wheels

Digitized by Google

per day. In the front part of the building, and running at right angles with the floors, is a track on which the ladle carriers run. These carriers are of iron, and carry the small ladles, which have a capacity of about 800lb. each, to the floors. The small ladles are operated by a small motor, which can be run by the man in charge of the large pouring ladle. A large electrically operated ladle, with a capacity of

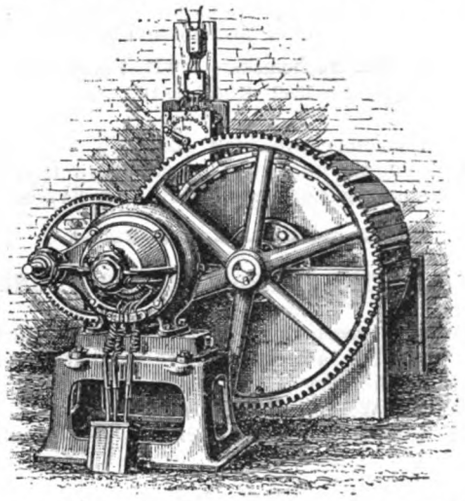

FIG. 2.—Electrically Operated Foundry.—Motor-driven Tumbling Barrel.

about 5 tons, is shown in Fig. 3. It is mounted on trunnions, and turned by the motor seen in the rear. The small ladles are carried to the front of the larger one, and each filled in turn and carried to the different floors. Over each floor is a track on which runs a small iron carriage. The carriage carries a steel cable, to which is attached an iron hook for lifting the ladles. There is also attached a cable for drawing the carriage back and forth over the floors.

150deg., but they do not give the slightest degree of trouble. They are all reversing, and equipped with controllers for reversing and varying speed. From each controller is run a hand-rope to the floor, so that each moulder has perfect control of the speed, and can vary it from 1ft. to 50ft. a minute on the hoist. Each hoisting motor is also equipped with an electric brake, which stops it instantly when the current is shut off, and also controls the lowering speed.

Directly under the motors and at right angles with the floors are the pits for annealing. There are three rows of pits, 20 pits in each. These pits, which are slightly larger than a car

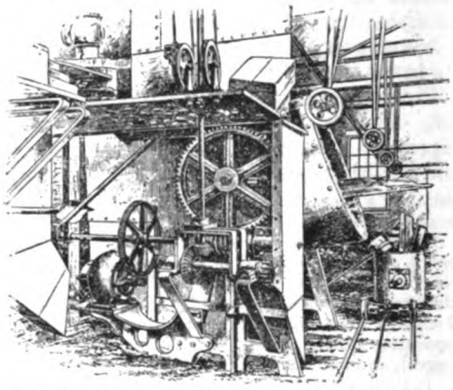

FIG. 3.—Electrically Operated Foundry.—Five ton Ladle Electrically turned.

wheel, are lined with fire-brick, and have each a capacity for accommodating 18 wheels. Leaving the moulds the wheels are carried along to the pits, in which they are placed by pitting cranes while still red hot. They are allowed to remain here several days for gradual cooling. Over each row of pits is a pack on which runs a carriage precisely similar to those running over the floors, and operated by motors in the same way.

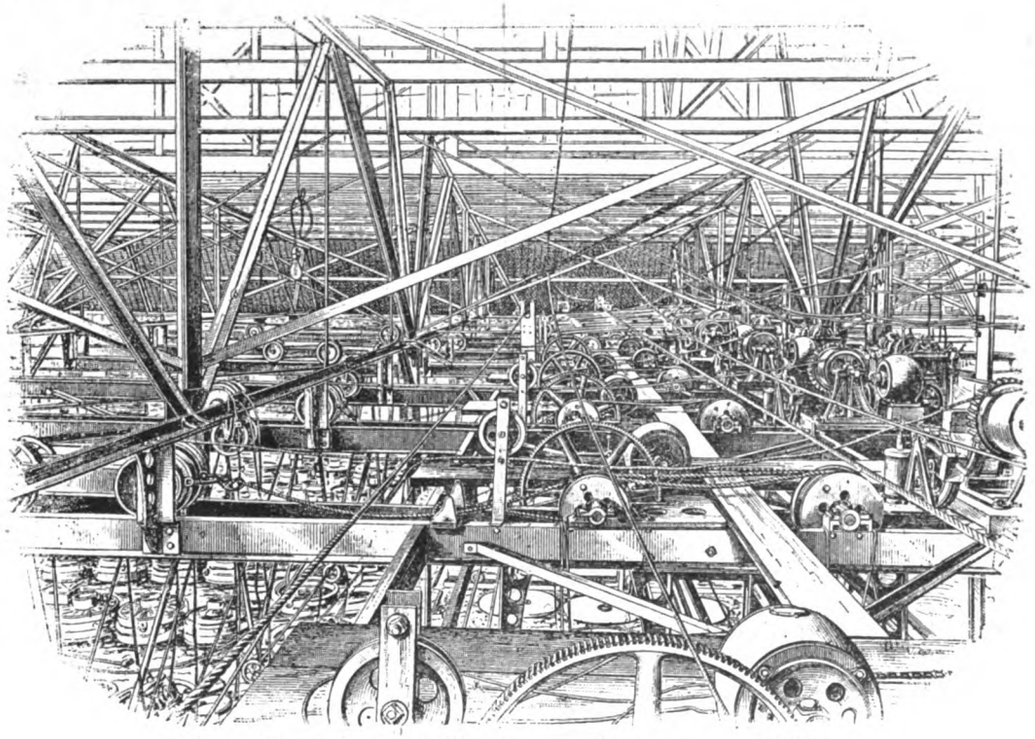

FIG. 4.—Electrically Operated Foundry.—Overhead Arrangement of Motors.

At the rear end of the building are located the motors for operating the system over the floors. The motors are shown in Fig. 4. There are two motors for each floor, one for operating the carriage, the other for the hoist. The motors were all built especially for the work they are required to do, and for the location, which required that they should be dust and heat proof. The temperature in their vicinity often exceeds

The current is distributed on the three-wire system. The motors are of 220 volts capacity, and are connected to the two outside wires. The plant has proved to be remarkably economical in operation, and the superintendent of the Company, Mr. Coleman, states that the running expenses have been much less than those of a similar plant operated by steam.

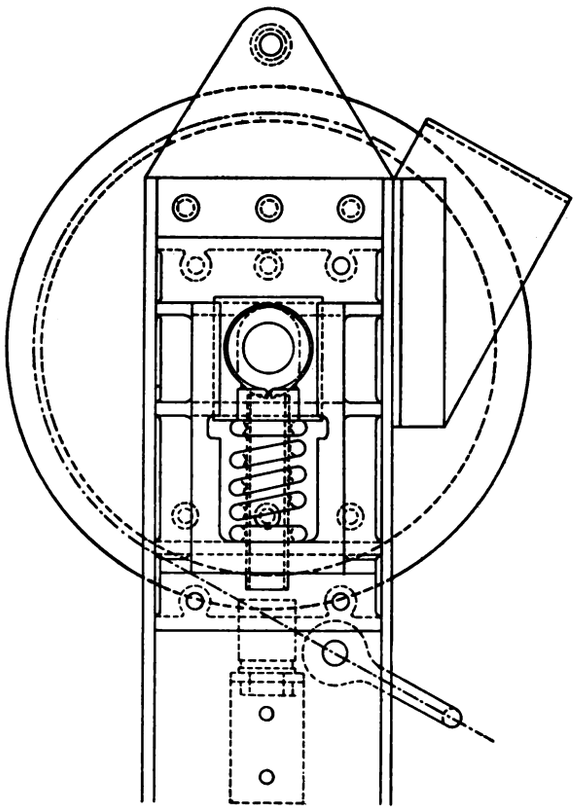
THE NEW ELECTRIC CRANES AT SOUTHAMPTON HARBOUR.

The completion and official trial, last week, of the new electric cranes erected by the Southampton Harbour Board, and their impending taking-over from the contractors, Messrs. Stothert and Pitt, of Bath, render opportune a description of these interesting machines and some account of the reasons which have led to their erection. We may say at the outset that, through the courtesy of Mr. J. G. W. Aldridge, the electrical engineer to the Southampton Harbour Board, we have recently had an opportunity of inspecting these cranes and of seeing them in operation. To him we are also indebted for the excellent photographs by Mr. J. M. Humby, of Southampton, as well as for the scale drawings, which illustrate this article.

In 1892, owing to the close competition between the harbour and the docks at Southampton, a Committee of the Harbour Board was formed which, together with Mr. Aldridge and Mr. W. Bowyer, the energetic traffic manager, visited several continental ports, with a view to discover the best means of expeditiously and cheaply handling cargoes by harbour cranes. Mr. Aldridge presented a report recommending the use of electric power, with the result that in 1893 the two 3-ton electric cranes described at that time in *The Electrician* were erected by Messrs. Statter and Co. So convinced did Mr. Bowyer quickly become as to the superiority in every respect of electrically-driven over every other kind of crane that he recommended an extension of the number of these cranes, and in 1896 specifications were drawn up by Mr. Aldridge and issued to contractors. The tender of Messrs. Stothert and Pitt, of Bath, was accepted for three 3-ton cranes and one combined 12-ton and 3-ton crane, the complete equipment being carried out for £7,288. Views of these new cranes, including a separate view of the combined 12 and 3-ton crane, accompany this article.



Jib End and Sheave, showing the Electrical Contacts, &c., for indicating Excess Load.

While the new cranes somewhat resemble in general appearance the older pair erected on another quay, they differ in many respects from these as regards essential points of detail. One of the most interesting of the new departures is the arrangement for automatically ringing an electric bell in the cabin when the crane is set to hoist too great a load. The sheave at the end of the jib, instead of being carried in a rigid bearing, has its bearings supported in guides on a steel coil spring. Excessive load compresses this spring sufficiently to close an electric circuit and ring a bell in the cabin. Another interesting feature attaches to the combined crane, the provision for which arose out of the necessity to have a 12-ton crane as a stand-by, although it would be infrequently used as such. Mr. Aldridge wisely decided not to have a separate stand-by crane, but to combine the 12-ton hoisting gear with a 3-ton crane; and this he has done by an ingenious arrangement of gears, whereby the motors are made to operate at will either the smaller or the greater hoist, the slewing gear being the same in both cases. Change from one hoist to another can be effected in 55sec., and is quite a simple matter.

The 3-ton cranes are constructed to lift 30cwt. at 200ft. per minute on a single rope, and three tons on a double rope at a proportionately lower speed. The radius of the cranes is 30ft., and the normal slewing speed 400ft. per minute with a 30cwt. load. Two separate electric motors operate the hoisting and slewing motions, the hoisting motor being rated at 50 H.P., and running at 600 revolutions per minute, and the slewing motor being rated at 10 H.P. The lifting motors of the 3-ton crane are not reversible, and have copper brushes on the commutators; the lifting motors for the 12-ton have carbon brushes, being reversible. The slewing motors are all provided with carbon brushes. All the motors were built by Messrs. Siemens Bros. and Co., and are of the two-pole drum-wound shunt-field type; they are supplied with current at 200 volts from the Corporation supply station. The pole-pieces are hinged to facilitate inspection. Upon the motor spindle is carried a Delta metal triple worm, gearing into a cut steel helical gear, the gear running in an enclosed oil bath. The gear wheel of the lift motor in the 3-ton cranes, carries the main drum, but in the 12-ton crane it actuates a throw-out back gear, similar to that employed in lathes, by which the interchange is effected. The back gear actuates either the 3-ton or the 12-ton hoist, the other hoist being locked.

The lever for working the hoisting motor, and the wheel for operating the slewing motor, in each case actuates automatically the regulating resistances of the motor fields. As the lever travels over it pushes a number of plugs resembling cornet pistons, these being thrown in *seriatim*, and each plug short circuits part of the resistance by a carbon contact. We believe this method was first adopted by Messrs. Siemens and Halske, of Berlin, by whom the regulators were supplied for these crane motors.

Each crane cabin is provided with a convenient switchboard, carrying the electric switches and Evershed indicating instruments. The field and armature switches are interlocked. In each cabin there are two 32 c.p. "Ediswan" glow lamps, also plugs for portable lamps, and near the top of the jib there is a group of glow lamps arranged in a reflector.

The manner in which current is led into the revolving cabin is of interest. In the centre of the floor there is an insulated box containing a brass ring rigidly fixed to the floor. Inside this ring, and pressing against the inner surface of the ring there is a copper brush of peculiar shape, rigidly connected to the stationary frame of the crane. This brush carries the current into the crane equally well, whether the cabin be stationary or moving in either direction. Current is brought to the crane through flexible diatrine cables, supplied by Messrs. W. T. Glover and Co. One end of the cable is attached to the crane; the other can be attached to any one of the connecting boxes along the quay. From the power station to the quay boxes the current is carried in bare copper strip laid in wooden troughs. The consumption of power is found to be from 3½ to 5 units per hour, and the present price charged is 3d. per unit, but it is expected that the price will shortly be reduced.

Even at the comparatively high price charged for current there is no doubt about the superiority of electric cranes for handling cargoes cheaply and quickly. Much more work can

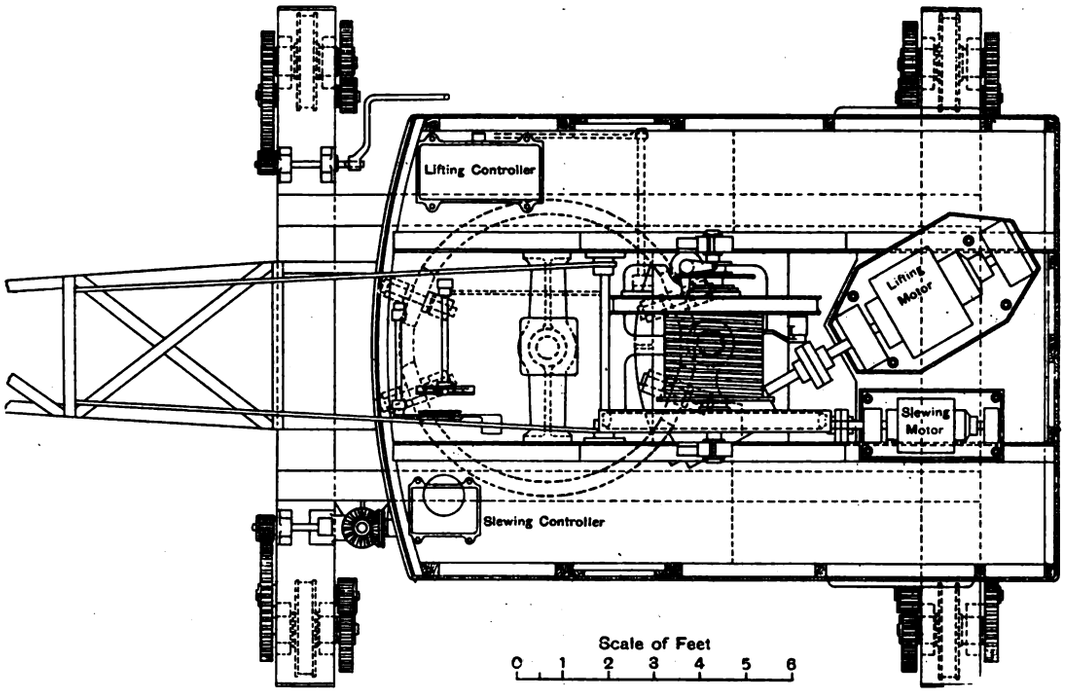
Four New Electric Cranes erected on Southampton Harbour Quay.

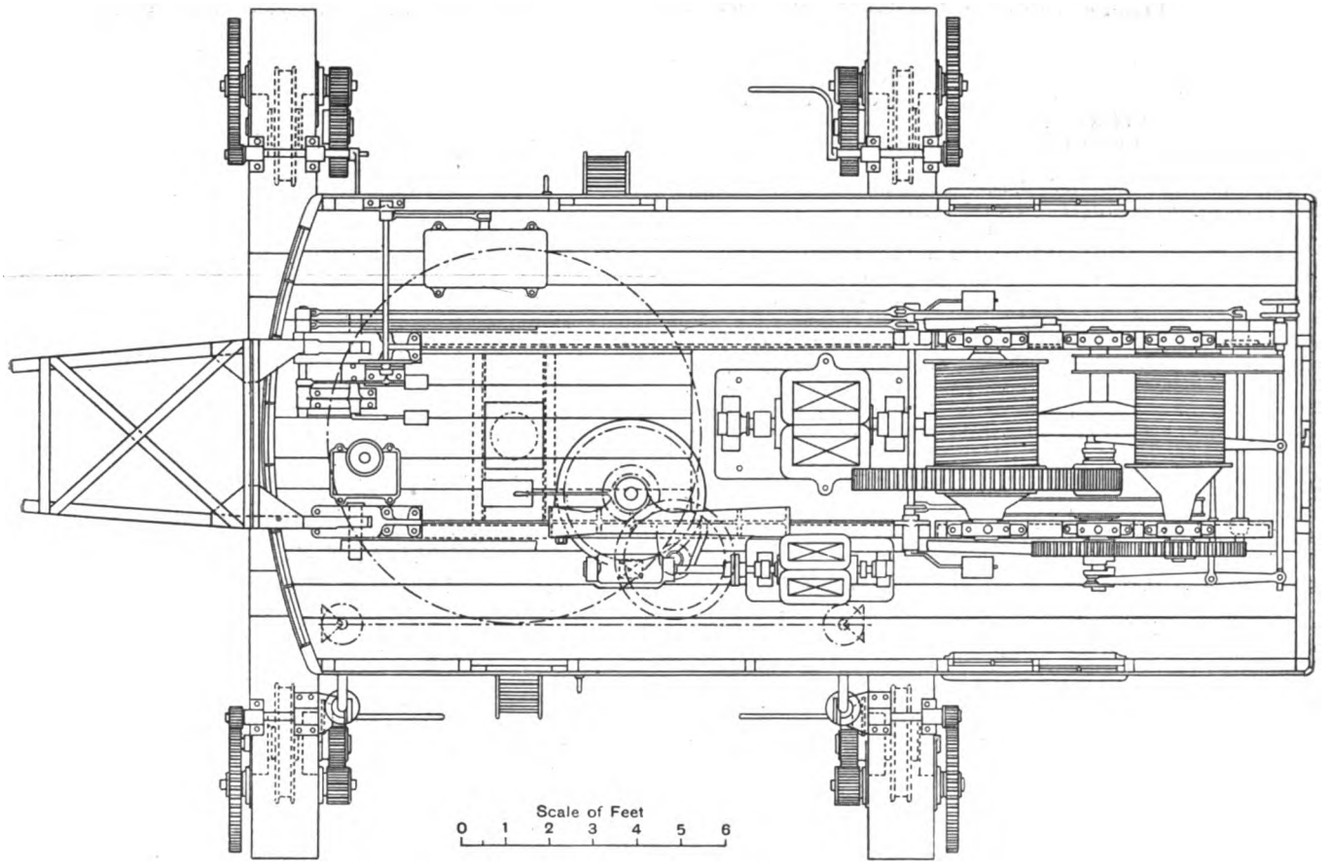
Combined 12-ton and 3-ton Electric Crane on Southampton Harbour Quay.

Digitized by Google

be got out of the cranes when in commission; they are less liable to get out of commission through breakdown, and are much more quickly repaired when breakdown occurs; and the cost of repairs is so trifling that at Southampton no separate account is kept of them. There is a great saving, also, in Southampton. Not only have men quite unskilled in electrical machinery been put in charge of the cranes, but they have acquitted themselves even better than the one or two men who possessed some knowledge of electric motors and their appurtenances. Curiously enough, the best craneman at South-



Plan showing Electrical Equipment of Cabin and Gear for the three 3-ton Electric Cranes at Southampton Harbour.



Plan showing Electrical Equipment of Cabin, Gear and Change-over Mechanism for the Convertible 12-ton and 3-ton Electric Crane at Southampton Harbour.

standing charges, since the same generating plant can be used—as it is at Southampton—for lighting the harbour and the town.

It is sometimes stated by parties interested in rival kinds of cranes, that electric cranes require specially skilled operators and cannot be safely placed in the hands of ordinary cranemen. This mythical notion has been completely exploded at Southampton—the man who "can make the cranes speak," who can get more out of them than anyone else—is a workman quite ignorant of electrical machinery: yet he has never had a breakdown; on the other hand, an electrical man who for some time had charge of the cranes was frequently responsible for interruptions. Facts like these speak for themselves.

ROTATORY CONVERTERS.*

BY PROF. SILVANUS P. THOMPSON.

So much interest is concentrated at the present time upon the transmission and distribution of electric energy for motive and locomotive power, as well as for lighting, that attention may profitably be directed to a class of machines which hitherto have been little discussed—namely, rotatory converters. In general a rotatory converter may be described as a machine having something in common both with a dynamo and with a motor so far as its structure goes, and of which the function performed by its rotation is to transform the electric energy which is imparted to it in one form into an output of electric energy of some other form. Of such converters there are many varieties, subserving many different uses. For example, one sort of rotatory converter will change continuous currents at one voltage into continuous currents at a different voltage. Another will change two-phase alternating current into three-phase alternating current. Another will change three-phase alternating current into continuous current. Yet another will change an alternating current of a certain frequency into an alternating current of a different frequency. In the following table of the principal conversions which may thus be accomplished, C stands for continuous current, A_1 for alternate current of single phase, A_2 for two-phase, A_3 for three-phase :—

Table I.

1. C to C at higher or lower voltage.	7. C to A_3, or A_3 to C.
2. A_1 to A_1 ,, ,,	8. A_1 to A_2, or A_2 to A_1.
3. A_2 to A_2 ,, ,,	9. A_1 to A_3, or A_3 to A_1.
4. A_3 to A_3 ,, ,,	10. A_2 to A_3, or A_3 to A_2.
5. C to A_1, or A_1 to C.	11. A_1 to A_1 of different phase.
6. C to A_2, or A_2 to C.	12. A_1 to A_1 of different frequency.

Any one of these conversions might be accomplished by selecting an appropriate motor to receive and be driven by the primary current, and coupling it to a generator to give out a secondary current of the species desired. It will be noted that of these conversions No. 2 is the ordinary alternate-current transformation, and is better accomplished by ordinary stationary transformers, as also are Nos. 3 and 4. By a suitable combination of stationary transformers No. 10 can also be effected, whilst Nos. 8 and 9 may be more or less satisfactorily effected by the use of auxiliary choking coils and condensers. But all of them may, and all the others must, be effected by means of rotatory apparatus. From the above list there have been omitted several possible cases of conversion, as, for example, that of a current supplied at fixed voltage, but of varying amperage, to a current of fixed amperage, but delivered at varying voltage.

It is not proposed here to deal, save purely incidentally, with the continuous-current transformer (No. 1 of the above table), which was brought before this Institution seven years ago by Major-Gen. Webber (Vol. XX., p. 63, 1891);† nor with phase transformers (Nos. 8, 9, 10 and 11); nor with frequency transformers (No. 12); nor with any stationary kind of transformer. This Paper will be directed to the machines devoted to the purpose of converting continuous currents into alternating currents of one, two, or three phases, or *vice versâ*. The importance which such machines have now assumed in the electrical industry arises from several causes. Long-distance transmission, with its corollary of the employment of high voltages, has demanded for this service alternating currents. The development of the electric tramway with continuous-current motors has called for methods of feeding at distant points. For this service rotary converters are required. Also for charging accumulators in cases where the public supply is an alternating one, and for factory driving with three-phase motors in cases where the public supply is one with continuous currents, rotary converters are wanted. All these cases might, of course, be met by the use of coupled machines, motor and generator. An early example of this method was afforded by the lighting station at Cassel, where the high-voltage alternating transmission was effected by the use of synchronous single-phase alternators, and the town distribution by continuous-current dynamos coupled to the shaft of the synchronous motors. Even now, in the case of a three-phase transmission and a continuous-current distribution, some engineers recommend the use of a group converter, consisting of a non-synchronous three-phase motor coupled to a continuous-current dynamo. But in all such cases the efficiency of the group is necessarily lower than that of either of its component parts. If a motor having, say, a 90 per cent. efficiency is coupled to a dynamo, also of 90 per cent. efficiency, the efficiency of the group cannot possibly exceed 81 per cent. Two other solutions to the general problem are possible. One is to wind the revolving armature with two sets of windings—one to receive the primary current and revolve as a motor, the other to generate the secondary current. As only one field magnet and one pair of bearings are required, there is an obvious economy of material, though no great saving in efficiency. Another solution—not, it is true, of universal application, but having the advantage of effecting a considerable increase of efficiency as well as an economy in material—is to wind the armature with but one set of windings, furnished at one end with a commutator, and at the other with appropriate contact rings, the same winding serving both to receive the incoming primary current and to generate the secondary current. It is this specialised type of machine which is the main subject of the present discussion, and which is called *par excellence* a rotatory converter.

At this point it may be convenient to drop the adjective "rotatory," and speak simply of *converters*, leaving the term "transformer" to denote the stationary apparatus.

Converters of a simple kind have been known for many years. Ever since 1885 there has been one at the Technical College, Finsbury, consisting of a bipolar Gramme machine with the ordinary commutator, with the addition of two insulated contact rings at the other end of the armature, these rings being connected to two points on the winding at opposite ends of a diameter. It, therefore, belongs to the species CA_1 (or No. 5 of Table I.). The addition of three contact rings connected to three symmetrical points on the winding would constitute a machine of the species CA_3 (or No. 7 of Table I.). It may be convenient here to point out the relation between the number of contact rings (called for brevity slip-rings) that are applied in any alternate-current generator, and the uses to which such generator may be put with respect to the phasal relations of the currents that may be drawn from it. For brevity these are enumerated in Table II. The figures in the second column relate to the angles between the points on the winding at which the slip-rings are connected for the simple case of a bipolar machine.

Table II.

No. of slip-rings.	Angle.	Possible service.
2	180°	Single phase.
3	120°	3 single-phase in ternature = "three-phase."
4	90°	2 single-phase in quadrature = "two-phase," or 4 single-phase in successive quadrature = "four-phase."
5	72°	5 single-phase in quinature = "five-phase."
6	60°	3 single-phase in ternature = three-phase with separate leads, or 6 single-phase in successive sexature = "six-phase," or 2 three-phase in sexature.
7	51⅐°	7 single-phase in septature = "seven-phase."
8	45°	4 single-phase in successive octature = "four-phase" with separate leads, or 8 single-phase in successive octature = "eight-phase," or 2 two-phase in octature.
9	40°	3 three-phase in nonature, or 9 single-phase in successive nonature = "nine-phase."

The general principles of conversion from polyphase to continuous currents, or *vice versâ*, are well known. The relation between the respective voltages on the alternating-current side and the continuous-current side have long ago been investigated, and expressions for their values in the several instances that may arise have been given for those cases in which it is assumed (*a*) that the alternating currents are simple sine functions of the time, and (*b*) that the magnetic flux is distributed as a sine function in space with respect to the periphery of the armature. Calculations for the voltages of two-phase and three-phase converters were given by Prof. Ayrton in the *Journal* of the Institution of Electrical Engineers, Vol. XXII., p. 340, in a discussion on April 27, 1893. For the purpose of studying such machines they may be considered either as used to convert continuous currents into alternating, or as converting alternating into continuous. The latter function is of more frequent occurrence in practice ; the former is rather more easy to follow out in thought. Taking, then, the instance of the converters as used to change continuous currents into alternating, and applying Prof. Ayrton's results to the several cases, we obtain the following numerical values. If we take the continuous currents as being supplied at a constant pressure of 100 volts, the voltmeter readings at the alternate-current side will be as given in Table III.

A very complete discussion of the voltage relations, with formulæ applicable to the cases of open-coil windings as well as of closed-coil windings, was given by Herr R. M. Friese, in the *Elektrotechnische Zeitschrift* of Feb. 15, 1894. Throughout the series of articles, he assumes the sine values of the distribution of the magnetic flux around the periphery of the armature. More recently, Mr. Steinmetz has reconsidered the same problem in the same journal in articles which appeared on March 3 and 10, 1898. From these theoretical considerations it is easy to write down, not only the voltages in the several cases, but also to calculate the corresponding relative values of the working currents in the armature and in the line wires. Similar calculations, down to a certain

point, have to be made by every designer of polyphase motors. If we assume the above values for the voltages, and proceed to calculate the corresponding currents for an output of 10 kilowatts, we find the value of the currents generated to be those in Table IV., the circuits being supposed non-inductive. Maximum as well as virtual values are given. Columns 4 and 5 refer to currents in the armatures, and columns 6 and 7 to currents in the lines. Star groupings are out of the question here, as they cannot be applied in armatures of converters. The only two-phase case that is possible is really a four-phase.

If the circuits are inductive, there will be a lag of phase in the currents, and wattless currents as well as working currents. For an equal output of power the numbers in columns 4 and 7 of the above table will need to be increased by dividing them by the cosine of the angle of lag.

Let us return to the problems presented by a converter, in which an armature, furnished with slip-rings at one end and a commutator at the other, is wound with but one set of windings, receiving current as a motor and delivering it as a generator. The question for consideration is how the current, in the act of being transformed from alternating to continuous, or *vice versâ*, flows through the windings of the armature. This is a matter that has not hitherto been considered in detail in any publication. Consider the general case of a revolving armature which is at the same time being traversed by continuous currents to drive it as motor, and by alternating currents which it is putting forth as generator. It is self-evident that the currents which it receives as motor must be flowing, in general, against the electromotive forces induced internally by its rotation, while the currents which it gives out as generator must be flowing with those electromotive forces. Further, since at every instant (under steady conditions of operation) the value of the continuous current is (by hypothesis) unvarying, whilst the instantaneous value of the alternating current is continually changing, it is clear that at some instants the motor current must be in excess of the generator current, whilst at other instants the reverse must be the case. Whilst the average speed of rotation remains uniform it is certain that during each period, or revolution, there will at times be a positive acceleration, and at other times a negative acceleration. Further, it is clear that if there are any irreversible sources of loss of energy, such as friction, hysteresis, or eddy-currents, the motor current must on the whole be greater than would otherwise be requisite, the power supplied at the motor side being greater than the output of power at the generator side, the difference being equal to the sum of the various items of power wasted in the machine. To make this clear, as well as to exhibit the way in which the circulation of current in the windings is effected, it is well to take some concrete case. All cannot follow an analytical argument; and, therefore, though the analytical treatment has many advantages, I have deliberately preferred, for the purposes of the present Paper, to avoid formulæ (though they have been used in its preparation), and, instead, to exhibit the arguments numerically by taking specific cases that are readily followed.

Let us consider a 10-kilowatt bipolar ring armature, having at its periphery 96 conductors, connected symmetrically down to a 48-part commutator, running at 1,200 revolutions per minute, or 20 revolutions per second. There will be two turns of the winding between each commutator bar and the bar next adjacent. (Or the armature might be wound as a lap-wound drum, with two conductors to constitute each element of the winding.) That it may run as a 100-volt continuous-current machine the magnetic flux through the armature core must be 5,208,333 lines, or a little over 5 megalines. Fig. 1 will serve to represent diagrammatically this armature when receiving 100 amperes at 100 volts, and running as a motor. The flow of current in the armature winding will, of course, be 50 amperes in each half of the ring.

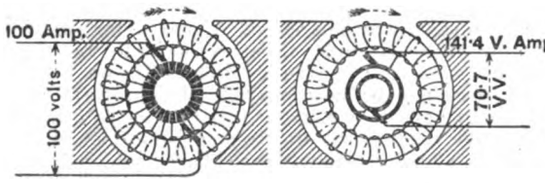

Fig. 1. Fig. 2.

Now, suppose a precisely similar armature to be revolving in a precisely similar field, but let its windings be connected at two diametrically opposite points to two slip-rings on the axis. If driven by power it will generate an alternating current. As the maximum voltage between the points that are connected to the slip-rings will be 100 volts, and the virtual volts (as measured by a voltmeter) between the rings will be 70 7 ($=100 \div \sqrt{2}$), if the power applied in turning this armature (Fig. 2) be 10 kilowatts, and if the circuit is non-inductive, the output in virtual amperes will be $10{,}000 \div 70{\cdot}7 = 141{\cdot}4$. If the resistances of each of the armatures is negligibly small, and if there are no frictional or other losses, the power given out by the armature which serves as

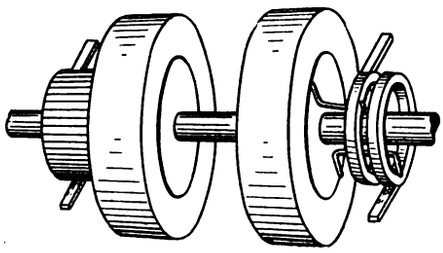

Fig. 3.

motor will just suffice to drive the armature which serves as generator. Accordingly, let us suppose them both mounted upon the same shaft, as in Fig. 3, and placed so that each lies in a similar and equal bipolar magnetic field. We have here the well-known combination of a *motor-dynamo*.* In every actual case there are, of course, losses (*a*) by friction, hysteresis, and eddy-currents, (*b*) by heating of the resistances in the armatures. The former have to be paid for by an increase in the motor current. Suppose them in the present case to amount to 4 per cent. for each armature, then 108 amperes instead of 100 must flow in from the supply circuit. The heat losses manifest themselves electri-

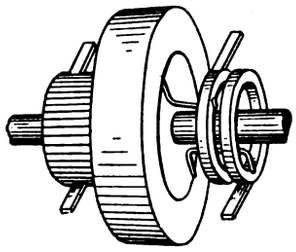

Fig. 4.

cally by a fall of potential at the terminals of the generator, and by a fall of speed in the motor if the primary voltage is not raised. Let the primary voltage be supposed to be raised the requisite small percentage to keep up the speed and to maintain the secondary voltage at 70·7 on the generator side: the output of the generator will then be 10 kilowatts, the input at the motor 10 kilowatts *plus* the number of watts required to make up all the various items of

* The term *dynamotor* is not only philologically bad, but is a misdescription. When two machines, of whatever kind, are thus coupled together, it is always the motor which drives the dynamo, not the dynamo which drives the motor.

lost power. Though the armatures are of equal resistance, and are respectively receiving and giving out (approximately) equal amounts of electric energy, the armature of the alternate-current side (whether used as generator or motor) will heat more than that of the continuous-current side; for it carries $\sqrt{2}$ times as large a current, and the ohmic heat will be proportional to the square of this, or twice that produced in the continuous-current armature by the 100 amperes of working current. In each armature the heat will be developed equally in all the separate coils around the ring. As the armatures are alike, and as the similarly placed windings in each are passing through identical magnetic fields, there is no reason why one winding should not answer for both purposes. Fig. 4 shows the case in which this change has been made. One armature only is used; it is connected at one end to the commutator, at the other to the two slip rings, and the machine now becomes a simple *rotatory converter*. The total hysteresis and eddy-current losses will obviously be now one-half of their former amount. The total heating due to resistance will be also reduced, because now the single winding has to carry only the differences of the two currents—a point presently to be considered—and the ohmic losses will be less. The waste of power, in fact, is approximately halved. How far this economy of losses can be carried depends on the number of phases of the alternating current. But there is another consideration involved—the question of armature reactions and sparkless collection of current. In the combined pair of machines called a *motor-dynamo* the brushes on the continuous-current side must be set, exactly as in any continuous-current machine, with a lead, negative or positive, according as whether it is operating as motor or dynamo. In the *rotatory converter* no lead in either sense need be given to the brushes; for the armature reactions of the motor part being, in general, opposed by those in the dynamo part, they cancel one another to a large extent. This property, which is common to all those motor-generators in which there is used, whether with one winding or two, a common core in a common field, was pointed out by the author* in 1888, when giving the theory of continuous-current transformers.

(*To be continued.*)

CORRESPONDENCE.

ELECTRIC CANAL HAULAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his letter on the above subject in your issue of Nov. 4th, M. F. Galliot takes exception to the statements in my Paper regarding the failure of earlier attempts to apply electric traction to canal haulage. I should like to point out that my remarks were in themselves perfectly correct; M. Galliot himself admits the unsuitability of his chain haulage system for general application.

When preparing the Paper, towards the end of August, I endeavoured to ascertain whether any other system had been successfully applied, with wholly negative results; the proceedings of the International Congress held in Brussels in the same month were not at that time accessible, nor have they as yet been published in our journals so far as I am aware.

With regard to the power required for haulage, ample data are available showing that on English canals, having a cross-sectional area four to five times that of the boats, one horse can haul a gross load of 120 tons at a speed of 2¼ miles per hour for four hours without difficulty. The pull, as measured with a dynamometer, is about 2lb. per ton, or 240lb. total at the outside. In my calculations I took 300lb. at a speed of 2½ miles per hour, the pull being increased in proportion to the square of the speed; the latter assumption is justified by experimental data in my possession. This pull, at the speed stated, is equivalent to two effective horse-power on the tow-rope; but it is specified that the motor shall be capable of exerting a pull of *twice* 300lb. when starting. In fact, the motor is 50 per cent. larger than is necessary for the power stated, though I expressly avoided rating it in horse-power, as this practice is misleading. A footnote to the Paper covers the case of canals of small cross-section, which were not discussed in detail for want of space.

I may add that the prevalent impression that the average horse can only perform ⅔ to ¾ of 33,000 ft. lbs. per minute is very much in error; a horse can work at the rate of 1½ mechanical horse-power for four hours per day, or 1 H.P. for eight hours per day, without injury, and can readily exert a pull of 600lb. for a short distance.

It would be interesting to hear how M. Galliot's tricyles pass one another on the towing-path; if the same delays occur as with horse haulage—at intervals of eight minutes from M. Galliot's data—there is little wonder that the (average?) speed does not exceed 1½ miles per hour!

The pull on the tow-rope equivalent to 6 effective horse-power, at a running speed of two miles per hour, is 1,125lb.; a much greater pull is necessary when getting up speed, so that the weight of the tricycles and the wear and tear on the tow-path must be very great. Also, a driver is indispensable on M. Galliot's system.

In conclusion, permit me to point out what M. Galliot has apparently overlooked—that the system I described is the invention of Messrs. Thwaite and Cawley; that my estimates were based on a yearly traffic of 30,000 barges, carrying three million tons, as compared with M. Galliot's 17,000 barges, carrying five million tons; and that the greater the traffic the less would be the cost per ton-mile on the Thwaite-Cawley system, which is particularly well adapted for heavy traffic.

—Yours, &c., A. H. ALLEN.

LEGAL INTELLIGENCE.

In re an Arbitration between South and the Mayor, &c., of Bedford.

This case came before the Court of Appeal (Lords Justices A. L. Smith, Rigby and Collins) on Monday, on the appeal of the Mayor and Corporation of Bedford from an order of Mr. Justice Phillimore in Chambers, by which he appointed an arbitrator under Sec. 5 of the Arbitration Act, 1889, under the alleged terms of an agreement made on July 24, 1897, between Mr. Harry South, electric light contractor, Garrick-street, London, and the Mayor and Corporation of Bedford, by which Mr. South agreed to execute certain works at the Newnham sewerage pumping station, Bedford, and provide motors coupled direct to two vertical spindle centrifugal pumps, the pumps to be capable of raising 750 gallons of sewage per minute.

Mr. ABEL THOMAS, Q.C., for appellants, said the matter first came before the Master in Chambers when he dismissed the summons. Mr. Justice Phillimore, however, on appeal by Mr. South reversed the decision of the Master, and made an order appointing an arbitrator. Under the contract or agreement Mr. South undertook to do the work for £600, 40 per cent. to be paid when the plant was put in, 40 per cent. when the work was completed, 10 per cent. six months after completion of the works, and the remaining 10 per cent. on the expiration of a period of maintenance. Disputes arose between Mr. South and Mr. Hope-Johnston, engineer to the borough of Bedford. One of the disputes was as to whether Mr. South was entitled to the second 40 per cent. on completion of the work. The answer to Mr. South's demand was that the works did not come up to the efficiency test, and, therefore, that Mr. South was not entitled to the £240.

Mr. NEALE said there was this further question—Mr. South said the plant was thoroughly efficient and up to the guaranteed efficiency, but Mr. Johnston said it was not.

Mr. THOMAS replied that it seemed to him that the only question their Lordships would have to decide was whether under the contract which was entered into between Mr. South and the Mayor of Bedford, Mr. Johnston was the arbitrator for the purpose of deciding that very question. The agreement provided that Mr. South was to execute the work in a good and workmanlike manner, and to the satisfaction of the borough engineer, and that each motor and pump should be capable of lifting 750 gallons of sewage a minute through the pipes. Another stipulation was that the waste of electrical power was not to be more than 40 or 50 per cent. "at full load." Exhaustive tests of the plant were to be made by the engineer or his representative at the contractor's expense, and such tests were to be carried out at such times as the engineer should decide, the contractor finding, if necessary, instruments and labour for the purpose of these tests. The contract further provided that the work was to be carried out under the direction or control of the engineer duly appointed by the local authority, and "to his entire satisfaction." A clause gave the Corporation power (if, in the opinion of the engineer, the work was not carried on properly or with due diligence) to serve the contractor with seven days' written notice to remedy defects, &c., with power at the expiration of that time to call in and employ another contractor to do the work left undone by the original contractor. Mr. Thomas said tests had been taken by Mr. Johnston, Mr. South having a representative present at the time, and the results of those tests were sent to Mr. South. Mr. Johnston, in the natural order of things, informed the Corporation of what had been done, and on May 18 formal notice was sent to Mr. South by the town clerk, who informed him that the plant had failed to pass the standard of test guaranteed in the con-

Digitized by Google

tract. Mr. South did nothing under the notice, and long after the expiration of the seven days the work was put in the hands of another contractor, and Mr. South had not been paid. Mr. South had, however, written to the Corporation several times, claiming that the work was of sufficient efficiency.

Lord Justice SMITH: Where is the clause that the engineer is to be arbitrator?

Mr. THOMAS: "The contractor will forthwith perform and execute the work in a good and workmanlike manner, and to the satisfaction of the engineer."

Lord Justice SMITH: That does not make him abitrator.

Mr. THOMAS: Well, if the work is to be done to his satisfaction he can decide whether it is to his satisfaction or not. That is conclusive, I submit.

Lord Justice COLLINS: "Arbitrator" is hardly the word for that.

Mr. THOMAS: Well, perhaps not; but he is "to decide and determine."

Lord Justice COLLINS: There is no power of appeal from his decision.

Mr. THOMAS: No, none.

Lord Justice SMITH: The point is this. You want it to go to the engineer?

Mr. THOMAS: It has been to him, and he has decided against Mr. South. My point is that Mr. Justice Phillimore was wrong when he ordered anything to be sent to arbitration. We say it is all decided. The learned counsel, continuing, said that the contract provided also that if any of the work or part of the works failed to pass the tests specified, the engineer might totally reject such work or part of the works. He could also during the progress of the works reject any of the materials brought on the site if, in his opinion, they were objectionable.

In answer to a question from the Bench, Mr. NEALE stated that what took place before Mr. Justice Phillimore when he made the order was this. The learned judge asked Mr. Jones, representing the Corporation, if his clients would reject the plant wholly or in part, and adjourned the hearing for a fortnight for an answer. Mr. Jones then informed the learned judge that his clients would not reject the machinery, but were acting under Clause 11, giving power to the Corporation to give notice of defects.

Mr. THOMAS said that had there been any other differences outside the power given to the engineer he agreed that the order of Mr. Justice Phillimore would be a right one. But there were no differences except as to the payments, and that was a point to be determined by the person agreed upon between Mr. South and the Corporation of Bedford, viz., Mr. Johnston. Mr. Johnston had not given his certificate.

Lord Justice SMITH: That is not the point. The question is whether it is to go to arbitration.

Mr. THOMAS: I submit there is nothing to arbitrate about.

Lord Justice SMITH: If my brother Phillimore's order stands what will be referred?

Mr. THOMAS: To ascertain, I suppose, the amount payable to Mr. South.

Lord Justice SMITH: No, that cannot be, because he has not got a certificate. That is no good to him. I suppose it will have to go to the arbitrator to decide whether the Corporation have broken the contract by taking the matter out of his hands.

Mr. DAVID JONES followed on the same side, and contended that nothing could be referred which was within the jurisdiction of the engineer under the contract, and that as the matter in dispute was within the jurisdiction of the engineer, Mr. Justice Phillimore's order was wrong, and ought to be set aside.

Mr. NEALE (on behalf of Mr. South) said that the words in the contract were not meant to apply to the contract as a whole, but to special powers by the contract given to the engineer, such as objection to materials, and so on.

Lord Justice SMITH: You have got to get within the arbitration clause. The engineer has to take the tests. What does he take them for?

Mr. NEALE: He has to satisfy himself that the machine is in good working order. But here is another difference. We are to supply machinery of good material and to execute the work in a workmanlike manner, to the engineer's satisfaction. The whole thing has been done under his supervision, and all the material passed through his hands on delivery.

Lord Justice SMITH: That may be; but they will not work.

Mr. NEALE replied that no objection was taken to the materials or machinery supplied or to the work done until the whole thing was completed, when Mr. South was entitled under the payment clause in the contract to have the certificate at once.

Lord Justice SMITH: If you perform your part of the contract, and the engineer says so, yes. But supposing he says you have not?

Mr. NEALE submitted that as soon as the work was completed and the machinery was ready to run, Mr. South was entitled to have the second 40 per cent. of the contract price. The remaining 20 per cent., which was due, was retained until the engineer had tested the efficiency of the plant. He (counsel) was instructed that no test had been made under specified conditions. The proper remedy under the contract was for the engineer to reject; there being a special clause providing for that contingency.

Lord Justice RIGBY: Do you mean to say that if he does not exercise the power of rejection there is no power at all?

Mr. NEALE said it seemed that if they got the goods and their engineer did not reject them, that they had no remedy. The plant was made up of different motors, &c., any one of which the engineer could have objected to and turned away. Mr. South had to obtain these things from different people and was, of course, liable to pay for them if not returned. They were bought by Mr. South under guarantees from the makers to perform the work. The proper course was to have a test made to see if the plant worked up to the guaranteed efficiency. Assuming even that Mr. South was wrong and that the plant would not work up to the guaranteed efficiency, if the Corporation elected to keep the goods, they must pay something for them, surely.

Lord Justice SMITH: Then sue them.

Mr. NEALE: We cannot in face of this arbitration clause. We took the only step we could in taking out this summons for arbitration. Here are things which Prof. Silvanus Thompson, or Prof. Kennedy, or any electrical expert could decide in half-an-hour.

Lord Justice SMITH: Will you take the decision of Prof. Silvanus Thompson?

Mr. NEALE: Yes, certainly.

Lord Justice SMITH: What do you say, Mr. Thomas?

Mr. THOMAS replied that it was too late to do so now, as the work had been let to another contractor and he understood that the whole condition of things was altered.

Mr. NEALE said he understood that at present nothing had been touched. It was quite true that a contract had been entered into with another contractor, but the other side had given an undertaking not to alter the work until this question was decided.

Lord Justice SMITH said that they must decide the case on the law.

Lord Justice COLLINS (to Mr. Jones): You have refused to reject?

Mr. JONES: Well, at present we want to see what we can use and what we cannot use, and we have not up to now made any use of any part of the machinery.

Lord Justice SMITH: I understand now why Justice Phillimore said, "If you will not reject, I will send the case to arbitration."

After further discussion, Lord Justice SMITH, in giving judgment, said: The question here is whether a builder or contractor can force to arbitration under an agreement he entered into with the Corporation on July 24, 1897. Mr. South contracted with the Corporation to put up some electrical pumps which were to work up to a certain test of efficiency in the contract, which I need not discuss. There was an engineer appointed by the contract who was to be the engineer of the works and to be the engineer of the Corporation of Bedford. Mr. South put up the pumps, and he was to be paid 40 per cent. of the contract price upon delivery of the things on the ground, 40 per cent. when the work was completed, and then afterwards the two remaining 10 per cents at the times specified. Mr. South was paid the first 40 per cent., and alleged that the second 40 per cent. had become payable because he had completed the work. The engineer, however, said it had not become due, because the work he had contracted to put up did not work up to certain tests, and, therefore, he would not give him a certificate for the second 40 per cent. Notice was given to Mr. South by the Corporation to go on with these works and make them efficient, but he had not done so. The Corporation then under the agreement had entered upon the works, and had entered into a contract with fresh contractors to complete the work to the satisfaction of their engineer. The engineer said that Mr. South had not completed the work according to the contract. Mr. South then said, "You have turned me out, pay me for the work I have already erected." He said, "You have taken these works over, pay me for what I have already put upon your premises." But the Corporation say no. "Well," says the plaintiff, "I will get an arbitrator appointed under the Arbitration Act, under this arbitration clause in the contract," and he gives notice to the Corporation to appoint an arbitrator. The Corporation decline to do so. He then goes to the Master, who declines to appoint any arbitrator, and then he appeals to Mr. Justice Phillimore, who did appoint the arbitrator. The Corporation said to the judge, "You cannot appoint an arbitrator, except as to disputes which are not within the jurisdiction of the engineer." Who is to ascertain the amount payable to Mr. South for the amount of work already done before it was taken out of his hands by the Corporation—perhaps, properly taken out of his hands? Why clearly not the engineer. There are certain matters in that clause which would be in the jurisdiction of the engineer, but not this matter. It seems to me, therefore, that there is a matter in dispute between Mr. South and the Corporation which does not come within the jurisdiction of the engineer, but is a matter of dispute on which the Court has jurisdiction to appoint an arbitrator, which my brother Phillimore has done. Mr. Justice Phillimore asked the Corporation if they would reject the plant, &c., which Mr. South had put up on this ground, and time was given to the Corporation to enable it to make up its mind. The Corporation turned round and said, "No, we will not," and then my brother Phillimore upset the Master, and set aside his order and ordered an arbitrator to be appointed. I think that that order was right under the circumstances, and that the appeal should be dismissed, with costs.

Lord Justices RIGBY and COLLINS fully agreed.

Mr. JONES: Will your Lordships specify the matter the arbitrator is to deal with!

Lord Justice SMITH: No (laughter).

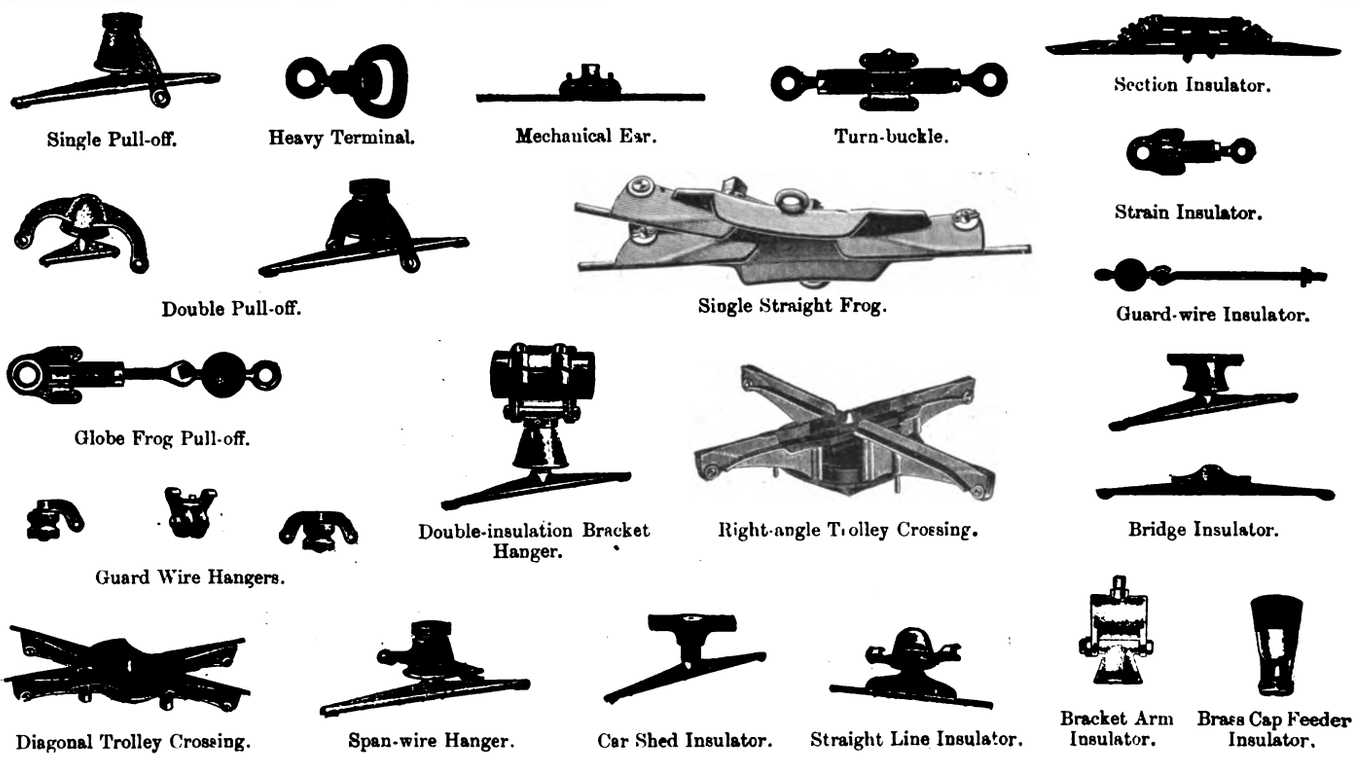
POSITION AND PROSPECTS OF ELECTRIC TRACTION IN THE UNITED KINGDOM.

The present position of the electric traction industry in the United Kingdom is decidedly one of great briskness, and the prospects are much more encouraging even than they were at the beginning of the year, and promise a long period of great activity in the construction of new electric tramways and railways. Some idea of the amount of work that has already been done in the United Kingdom may be gathered from the following list of complete lines in operation, which have been described in *The Electrician*:—

Brighton	Sept. 1, 1883	Bristol—Kingswood	Oct. 18, 1895
Giant's Causeway	Oct. 27, 1883	Coventry	Nov. 22, 1895
Blackpool	Sept. 10, 1886	Dublin—Dalkey	Jan. 17, 1896
Shoreham—W. Brighton	July 29, 1887	Douglas Head	Dec. 4, 1896
Ryde Pier	Feb. 15, 1889	Bristol—Eastville	Feb. 5, 1897
Carstairs	May 10, 1889	Leeds	Nov. 12, 1897
Birmingham — Bournbrook	July 25, 1890	Cork	Dec. 24, 1897
Southern Pier Elec. Ry.	Aug. 22, 1890	Dublin—Clontarf	Dec. 24, 1897
City & S. L. Railway	Nov. 7, 1890	Kidderminst'r-St'rp'rt	May 20, 1898
Guernsey	April 3, 1891	Hartlepool	June 19, 1898
Leeds	Oct. 30, 1891	Halifax	July 8, 1898
Liverpool Overhead Ry.	Feb. 10, 1893	Waterloo and City	July 15, 1898
Douglas—Laxey	Aug. 17, 1894	Middlesbro' — Stockton—Thornaby	July 29, 1898
Snaefell Mountain	Sept. 13, 1895	Douglas-Laxey-R'ms'y	Aug. 8, 1898

Overhead Trolley Equipment, Bonds, &c.—The overhead trolley system stands *facile princeps* among electric traction systems, and, indeed, claims the lion's share of the work. The number of British firms who undertake the manufacture of overhead trolley equipments, bonds, &c, is comparatively small, but among these we may mention the ubiquitous ROBERT W. BLACKWELL AND CO.; MACARTNEY, MCELROY AND CO.; and Messrs. W. F. DENNIS AND CO., who have all done a very large amount of this class of work.

Poles, Rails, Points, &c.—Although competition with British manufacturers is not altogether absent, contracts for these details remain largely in the hands of British makers. Among these Messrs. ASKHAM BROS. AND WILSON, the BARROW HÆMATITE CO., &c., are carrying out large contracts, and have done so in the past for rails, bonds and special work in tramways and light railways; and Messrs. JOHN SPENCER, Messrs. MACFARLANE AND CO., the MANNESMAN TUBE CO., the LEEDS STEEL WORKS, HADFIELD'S STEEL FOUNDRY CO., and Messrs. MORRIS, TASKER AND CO. have supplied many thousands of centre and side poles for various systems of overhead trolley construction.



OVERHEAD TROLLEY DETAILS.

In order to show the enormous amount of work that is being done in connection with electric traction at the present time, and to give some idea of the great variety of industries affected, and the large number of firms who are engaged in this work, we have prepared below some account of the various departments of electric traction constructive work:—

Complete Railways and Tramways.—The number of British and American firms who have actually undertaken complete equipments for railways and tramways in the United Kingdom is considerable, and is increasing every month. Among these we may notice Messrs. MATHER AND PLATT, who supplied plant for the City and South London Railway, the Fleetwood inter-urban line, the Douglas (Isle of Man) line, &c.; the ELECTRIC CONSTRUCTION CO., who were prominently connected with the equipment of the Liverpool Overhead Railway and several later electric tramway projects; Messrs. SIEMENS BROS. AND CO., who built the earliest locomotives for the first underground railway in London, as well as for the Waterloo and City Railway; Messrs. CROMPTON AND CO., who from the earliest were connected with both underground and surface work; the BRUSH CO. at Dover and Kidderminster; the THAMES IRONWORKS; besides the following firms associated with American manufactures, viz., the BRITISH THOMSON-HOUSTON CO., the WESTINGHOUSE CO., and Messrs. R. W. BLACKWELL AND CO. We must not forget to mention the BRITISH ELECTRIC TRACTION CO., who are actively engaged in the promotion of new electric tramways and railways all over the country, although not actually engaged in manufacturing and construction work.

Cars and Locomotives.—There is a considerable opening for British industry in the special manufacture of electric cars and locomotives, either the complete vehicle, the car body, or the special form of truck which electric traction renders necessary. Among British makers engaged in this work we may mention SIEMENS BROS. AND CO., CROMPTON AND CO., the BRUSH COMPANY, MATHER AND PLATT; and the ELECTRIC CONSTRUCTION CO., for locomotives and motor cars; and MILNES AND CO. and DICK, KERR AND CO. for tramcars. In this country the short double deck rigid truck car is more popular for tramways than the Pullman type of American car on double bogies, but this latter is gaining ground, and with the inevitable increase in the volume of traffic to be handled by electric lines will, we think, become increasingly popular here. The trucks commonly used on both kinds of car are exemplified by the Peckham cantilever and bogey trucks shown in the accompanying illustrations.

Digitized by Google

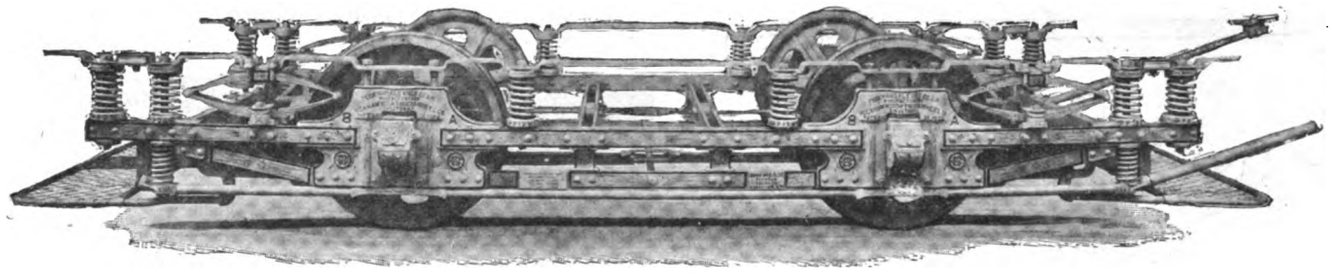
Car Motors.—Electric traction has developed a distinct type of electric motor, partly from the necessity of withstanding the heavy wear and tear, and partly in order to provide a motor without any external field, since heavy stray fields would be objectionable on account of their effect on passengers' watches, &c. Among the English firms who have supplied railway and tramway motors are Messrs. SIEMENS BROS. AND CO., CROMPTON AND CO, the ELECTRIC CONSTRUCTION CO., the BRUSH COMPANY, MATHER AND PLATT, while from America we obtain the THOMSON-HOUSTON, WESTINGHOUSE, and WALKER types of motors. The gearless motor for tramway work has not yet arrived, and it is doubtful if it ever will, but for heavy railway work ungeared motors have been very successfully used in this country.

Cables.—In British traction work, cables are usually provided both for the supply and return. Notwithstanding that the return current is thus provided with an insulated conductor, care has to be taken to keep down electrolytic and other objectionable effects of stray currents. In connection with this branch we may mention that the BRITISH INSULATED WIRE CO. has recently introduced an ingenious system of laying cables for tramway work, the object being to do away with the electrolytic action of return currents on the tramway cable and its lead covering. The lead-covered cable is laid in earthenware troughing of substantial section, the troughing being provided with small bridge pieces at intervals to keep the cable clear at the bottom of the troughing, which is then filled up with a pitch composition, and a substantial cover securely fastened on the top. In this system, therefore, there is copper, paper and lead in the cable itself, with pitch and earthenware as a protection, which renders the job practically imperishable. The CALLENDER CO. are doing extensive work in laying cables for tramways in this country, and are introducing a variety of systems adapted to various classes of work and to varied local conditions. Their work is so well known among electrical engineers and to the general public, that a detailed account of these systems would be superfluous. Other leading firms supplying cables of excellent quality for traction work, and whose manufactures may be thoroughly relied upon, are Messrs. SIEMENS BROS. AND CO., the TELEGRAPH MANUFACTURING CO., the SILVERTOWN CO., HENLEY'S TELEGRAPH WORKS CO., W. T. GLOVER AND CO, W. F. DENNIS AND CO., CONNOLLY BROS., JOHNSON AND PHILLIPS, and the SOCIÉTÉ D'EXPLOITATION DES CABLES ELECTRIQUES.

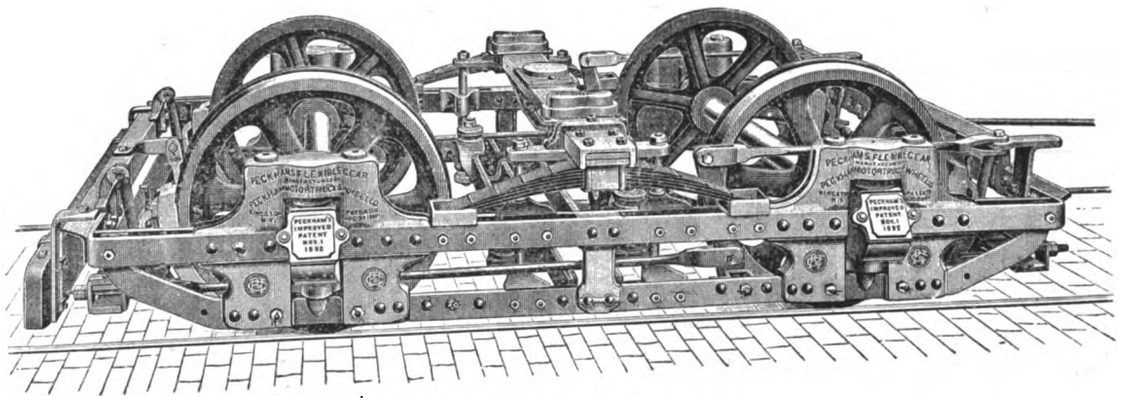
Cable Conduits.—Some cables go in conduits, others are buried by the "undertakers." Where a conduit is to be provided engineers cannot do better than employ one or more of the following firms, viz., Messrs. DOULTON AND CO., whose excellent stoneware conduits are largely in demand; Messrs. JOHNSON AND PHILLIPS, who have a well-known "BROOKS" system of oil insulation conduits; Messrs. CROMPTON AND CO., who laid bricks in the form of conduits in the early days and have successfully stuck to the practice ever since; also the BRITISH INSULATED WIRE CO., whose latest and undoubtedly excellent conduit we describe in the previous paragraph; and the CALLENDER CO.

Batteries.—Engineers are divided as to the advantages of using batteries on tramway circuits, but there is no doubt that they have been used with great success on many lines. The E.P.S. COMPANY'S battery at Liverpool is one of the largest in the world for tramway work. The CHLORIDE SYNDICATE have constructed a large number of storage batteries, notably at Leeds and the Isle of Man. The TUDOR ACCUMULATOR CO'S. battery is also a well-tried accumulator for this class of work, and other makers are the D.P. BATTERY CO., Messrs. PRITCHETTS AND GOLD, and the HART SECONDARY BATTERY SYNDICATE.

Dynamos.—Upon the reliability of the tramway generator the success of a tram line must depend as much as upon any other detail, if not more. Indeed, reliability must be placed in front of economic working. Manufacturers everywhere have paid special attention to the construction of railway generating plant. Among the firms who have done this are SIEMENS BROS. AND CO., MATHER AND PLATT, ELECTRIC CONSTRUCTION CO., the BRUSH COMPANY, P. R. JACKSON AND CO., CROMPTON AND CO. and THOMAS PARKER (Limited); while, of course, the generators from America supplied by the WESTINGHOUSE and BRITISH THOMSON-HOUSTON CO.'S are also well known. There is a considerable opening for polyphase generators in regard to long traction lines in the future, and it is probable that great development in this class of generator will shortly have to be recorded.



"Peckham" Cantilever Rigid Truck.



"Peckham" Bogey Truck.

Steam Engines.—A considerable variety of type of steam engine is in use for tramway work. These may be divided into high speed engines, of which Messrs. WILLANS AND ROBINSON, Messrs. BELLISS AND CO. and the BRUSH COMPANY have supplied large numbers, and low speed engines, either geared or direct-coupled. Among makers of low speed engines we may name Messrs. GALLOWAYS, JOHN FOWLER AND SONS, MARSHALL, SONS AND CO., PLENTY AND CO., MCLAREN AND CO.; the MIRRLEES, WATSON AND YARYAN CO., Messrs. CLARKE, CHAPMAN AND CO, ALLEY AND MACLELLAN, BUMSTED AND CHANDLER, CLAYTON AND SHUTTLEWORTH, DAVEY, PAXMAN AND CO., RANSOMES, SIMS AND JEFFERIES, W. H. ALLEN, SON AND CO., ROBEY AND CO., RUSTON, PROCTOR AND CO, RICHARD HORNSBY AND SONS, ALEX. SHANKS AND SON, CLENCH AND CO. and BROWETT, LINDLEY AND CO. are also manufacturing high speed engines suitable for traction work. The Westinghouse engine is also being used in the United Kingdom. Messrs. ROBERT W. BLACKWELL AND CO. have introduced here the horizontal direct-coupled steam engine of MACINTOSH, SEYMOUR AND CO. and the ALLIS engines, the last named being also made in the vertical pattern. A well-known rotatory form of

Digitized by Google

steam engine is manufactured by C. A. PARSONS AND CO., and is largely used in power stations.

Boilers.—Steam generation is a problem which had been fairly well threshed out by electric light engineers in this country before the advent of electric traction, and the types of boiler employed are very similar in the two cases. The Babcock-Wilcox water-tube boiler is largely used, as also is the "Economic" boiler of Messrs. DAVEY, PAXMAN AND CO., while Messrs. RUSTON, PROCTOR AND CO. manufacture a form of return tube boiler which is doing good service in power stations. Some engineers prefer the Lancashire type of boiler, as having a greater capacity for steam generation, and among the firms who are working this type of boiler for traction work we may mention Messrs. ROBEY AND CO., of small details, and Messrs. HOLDEN AND BROOKE are doing good service in supplying first-class equipments of steam traps, steam dryers, and anti-primers, purifiers and auxiliary plant of all descriptions. Plant for producing forced draught in the boilers is a matter of great importance where rapid steam production at short notice is required, a condition which is often to be met with in tramway power stations. The centrifugal type of fan is extensively patronised, and it will be seen in the article describing the Chicago railway that the Sturtevant fan is used there. This particular make of fan is also being largely adopted for British power stations, and is supplied in this country by the STURTEVANT ENGINEERING CO. The CROSBY STEAM GAGE CO. supply high-class details of steam auxiliary plant of all descriptions, including valves,

RAIL BONDS.

YATES AND THOM, GALLOWAYS, JOHN FOWLER AND CO. (Leeds), TINKERS (LIMITED), and CLARKE, CHAPMAN AND CO.

Auxiliary Steam Plant.—There is much variety in the auxiliary steam plant necessary in a modern electric power station. The practice of driving pumps by steam is not always resorted to, many engineers having a preference for the electric pumps manufactured by the ELECTRIC CONSTRUCTION CO., while others adopt the direct duplex form of pump manufactured by the WORTHINGTON PUMPING ENGINE CO., the BLAKE AND KNOWLES STEAM PUMP WORKS, the popular type supplied by the PULSOMETER ENGINEERING CO., and W. H. WILLCOX AND CO. Considering the immense importance of supplying to the boilers constant feed which is not liable to break down, the advantage of adopting reliable steam or electrically-driven feed pumps is of greatest importance, and engineers should invariably adopt the manufactures of the best firms in this class of business. The success of steam plant not infrequently depends upon the smooth working gauges, &c. Lubricators and general engineering stores are a feature of the business of Messrs. W. H. WILLCOX AND CO., and the UNITED ASBESTOS CO., both of which firms, with Messrs. ENGELBERT AND CO. and Messrs. SNOWDON, SONS AND CO., supply lubricants to the majority of power stations.

Condensers.—The economy of condensing has led to the adoption of condensers in the majority of power stations. Of the various types of surface condensers those made by the WORTHINGTON PUMPING ENGINE CO., Messrs. LEDWARD AND CO., Messrs. KIRKALDY AND CO., the WHEELER CONDENSER AND ENGINEERING CO., Messrs. CLENCH AND CO., and Messrs. W. H. ALLEN, SON AND CO. are extensively used. The "Ejector" condenser, owing to its compactness and efficiency, is also very largely used, the favours being distributed between the "Ejector" condenser of Messrs. LEDWARD and that of Messrs. KÖRTING BROS.

Gas Engines.—In this department of electric power work, the names of Messrs. CROSSLEY BROS. stand pre-eminent. Other firms

Digitized by Google

include Messrs. Robey and Co., Tangyes (Limitbd), Dick, Kerr and Co, and J. E. H Andrew and Co. The Dowson Economic Gas and Power Co. supply gas-generating plant for these engines.

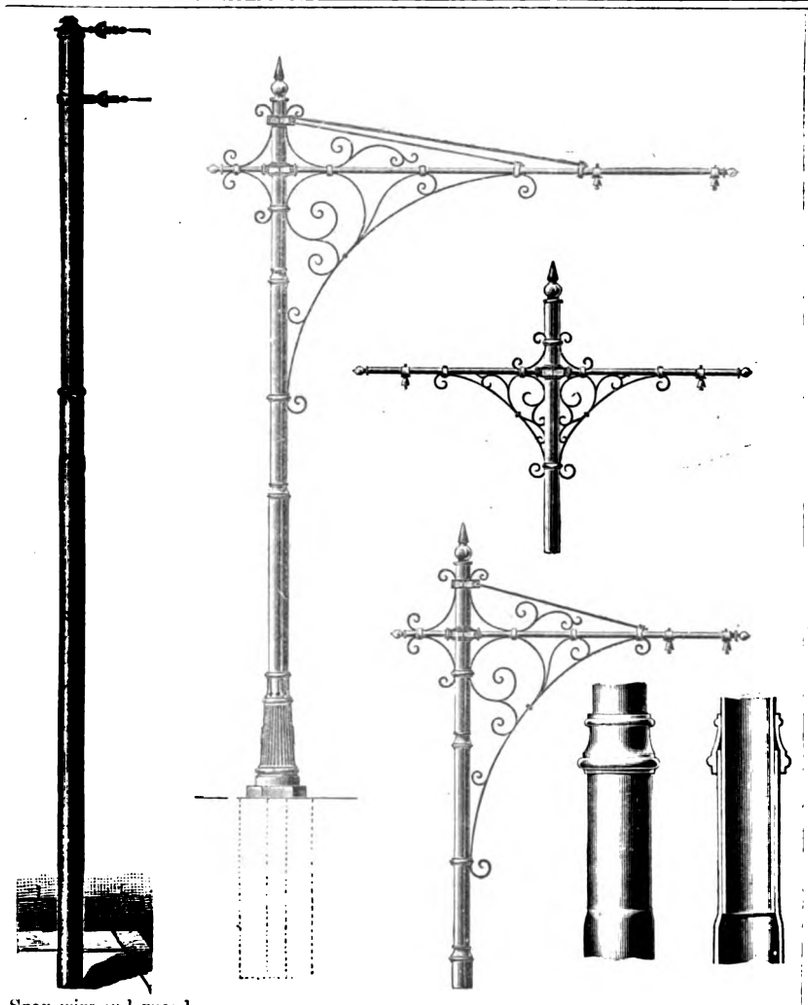
Turbines and Water Wheels.—Water power is not extensively available in this country, but for localities favoured with this source of power, engines are supplied by the following firms:—Messrs. Gilbert Gilkes and Co., Carrick and Ritchie, F. Nell, S. Howes, Fraser and Chalmers, and W. Gunther and Sons.

Switchboards, Instruments, &c.—While many manufacturers contract for the supply of entire switchboards, others manufacture only the switches and instruments which are mounted upon them. Among the firms supplying instruments, switches and complete equipments in this class of plant may be mentioned the Telegraph Manufacturing Co., the Electric Construction Co., the Edison-Swan Co., the Silvertown Co., Messrs. Siemens, Bros. and Co, Crompton and Co., Dorman and Smith, Nalder Bros. and Co., Eversbed and Vignoles, O. Berend and Co., Nalder Bros. and Thompson, Elliott Bros., Drake and Gorham, J. H. Holmes and Co, James White, Williamson and Joseph, the General Electric Co, H. M. Salmony and Co., J. Davis and Son, Spagnoletti and Crookes, A. P. Lundberg and Verity's, Limited; also the Electrical Power Storage Co., the Brush Co., the Westinghouse Co. and the British Thomson-Houston Co.

Meters.—It frequently happens that the power station is owned by a body different from that owning the tramway, and power is metered out from the station to the line. The types of meter extensively used for this purpose are somewhat varied, and include the well-known meters of Ferranti, Thomson, Aron, Chamberlain and Hookham and Schallenberger.

Auxiliary Electrical Plant.—Besides the plant and apparatus directly required for traction work, there is a good deal of electrical apparatus that is used contingently, such, for instance, as where arc lamps are placed on trolley poles. The enclosed arc lamps of the Davy Electrical Construction Co. and the Jandus Company are being largely used in this connection, as also are the open types of arc lamp manufactured by Messrs. Crompton and Co., the Brockie-Pell Co. and Messrs. Johnson and Phillips. For the interior of cars and power stations, &c., glow lamps are more commonly used, the Ediswan, Sunbeam, Stearn, Robertson, Pope and similar lamps of high candle-power being in general favour. It is one of the blessings of electric traction that it enables cars to be lit with a profusion of good light instead of by dingy oil lamps, a blessing that is specially appreciated by the public who ride in tramcars.

While the foregoing summary of the work which is being done in connection with electric traction enterprise in this country does not pretend to give a complete account of all the firms who are engaged in this work it may be taken as fairly representative of the various departments and of the leading firms engaged in these. There are naturally a large number of non-electrical industries which from lack of space we are unable to mention, and as the applications of electricity for traction work, both on rails and on ordinary roads, become more and more extended the number of firms working in each department, as well as the number of these departments, must inevitably increase. We can conclude this short *resumé* by assuring our readers that at no time in the history of electrical engineering have the prospects of any department been brighter than they are to-day.



Span-wire and guard-wire Side Pole.

Centre and Side Trolley Poles with Double and Single Brackets.

"Modern Opera Houses and Theatres."—This portentous work, of which Mr. Edwin O. Sachs is the author, is in three large volumes, 23in. by 16in., containing in all 450 pages of text, 220 plates and 1,050 diagrams, is announced as now ready. The work, which contains special matter relating to lighting, heating and ventilation of theatres and public halls, is published by Mr. T. Batsford, 94, High Holborn, W.C.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition ready in November.*

"Practical Notes for Electrical Students."—By Messrs. A. E Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition,* 2s. 6d. net, 2s. 9d. post free.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97.' A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"Electromagnetic Theory."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

Extension of Time.—The *Salford* Electric Lighting committee invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walness-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, *by Dec. 15, not Dec. 1, as originally advertised.*

Tenders are invited by the *Board of Control, Dublin,* for the supply of the necessary plant, wiring, &c., for the electric lighting of Richmond District Lunatic Asylum. Plans and specifications can be seen at the offices of the electrical engineer, Mr. Walter Leake, 51, Victoria-buildings, Manchester, and of Mr. W. H. Byrne, 20, Suffolk-street, Dublin. Further particulars are given in our advertisement columns, and tenders addressed to the secretary (Mr. H. Williams), Custom House, Dublin, must be in by 10 a.m. of Dec. 5.

The *Beckenham* District Council invite tenders for the supply of the following electric lighting plant:—(*a*) Water-tube boilers and economiser; (*b*) steam alternators, transformers and switchboard; (*c*) pipework, feed pumps, overhead tank, feed-water heater, &c.; (*d*) arc lamps, lamp posts, &c.; (*e*) cables and street work; and (*f*) travelling crane. Specifications, &c., can be obtained after the 21st inst. from the consulting engineers (Messrs. Wilson and Story), 66, Victoria-street, London, S.W. Further particulars are set out in an advertisement elsewhere, and tenders must be sent to the clerk to the council (Mr. F. Stevens) by noon of Saturday, Dec. 17.

The *Shanghai* Council also invite tenders for a concession, for a period of 30 years, for the exclusive right of establishing and working a telephone system in Shanghai. Further particulars are set out in an advertisement on another page, and plans may be seen, and particulars obtained on application to Messrs. John Pook and Co., 8, Jeffrey's-square, St. Mary Axe, London, E.C. Further information may be obtained on application to Mr. Charles Mayne, municipal engineer, Shanghai, whose telegraphic address is "Dynamo Shanghai." Tenders must be sent to the secretary (Mr. J. O. P. Bland), Shanghai, by noon of Friday, March 31.

The *Shanghai* Municipal Council invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system in the streets of Shanghai. Tenderers can obtain particulars on application to Messrs. John Pook and Co., 8, Jeffrey's-square, St. Mary Axe, London, E.C., and all further information can be obtained on application to Mr. Charles Mayne, municipal engineer, Shanghai, China. Tenders have to be sent in to Mr. J. O. P. Bland, secretary, not later than noon of Wednesday, March 15, 1899. Some further particulars will be found in an advertisement on another page.

As announced in our advertisement columns, the Directors of the *Great Northern Railway Co.* invite tenders for the supply of new, and the purchase of old, stores for 12 months from Jan. 1. The list of contracts and separate forms of tender for each may be obtained on application to Mr. Weeks, Stores Superintendent, Doncaster, by whom all information will be furnished. Patterns will be exhibited at the Stores Department, where they may be inspected from 21st inst. to 5th prox. inclusive. Tenders, addressed to the Stores Committee, must be sent to the Company's offices at King's Cross, London, N., by 10 a.m. on Tuesday, Dec. 6.

The *Glasgow* Corporation invite tenders for supplying switchboards and instruments at the new electricity works, Port Dundas. Tenders to town clerk (Sir J. D. Marwick) by Dec. 5.

The *Glasgow* Corporation also invite tenders for the supply of about 800ft. of cast-iron pipes (21in. diameter) and certain cast-iron pipes (22in. and 29in. diameter), with special castings, for the Port Dundas electricity works. Tenders to town clerk by 22nd inst.

The Corporation of *Blackpool* invite tenders for trolleys, trolley wire and other material in connection with the conversion of their present conduit to the overhead system. Tenders by Nov. 22.

The *Dublin* United Tramways Co. invite tenders for the supply of general stores, including electrical supplies, car fittings, ironmongery, &c., for the year 1899. Tenders to the chairman of the Company, 9, Upper Sackville-street, Dublin, by 5th prox.

Digitized by Google

The Electric Lighting committee of the borough of *Middlesbro'* require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers and accessories, mechanical stokers, feed pumps, injector, economiser and electric motor; (*b*) slow speed steam dynamos and accessories; (*c*) condensing plant and pipe work; (*d*) overhead travelling crane; (*e*) switchboard and instruments; (*f*) accumulators; (*g*) trenching, cables, &c.; (*h*) meters. Tenders to Mr. Geo. Bainbridge, Municipal Buildings, Middlesbro', by Nov. 29.

The *Leatherhead* District Council invite offers from persons willing to take over their Electric Lighting Order (1898). Offers to Council Offices, Leatherhead, by Nov. 21.

The *Great Northern Railway Co.* (*Ireland*) require tenders for the erection of an electric power station, brick chimney, &c., at Sutton, Co. Dublin. Tenders to secretary by Dec. 5.

The *Waterloo-with-Seaforth* (*Lincs.*) District Council require tenders for the supply of 16 arc lamp columns and carriers. Tenders to Town Hall, Waterloo, by noon 26th inst.

The *Wincanton* (*Bath*) Parish Council require tenders for public lighting, with gas or other illuminant, for one year from Nov. 30. Tenders to clerk by 26th inst.

Tenders are invited by the municipal authorities of *Aurich* for the erection of an electricity supply station, coal, gas or acetylene gas works in the town. Plans and tenders to Der Magistrat der Stadt Aurich, Germany.

The municipal authorities of *Anzin* (*Nord*) invite tenders until the 28th inst., for the concession for the lighting of the town by electricity or gas for 40 years. Tenders to La Mairie d'Anzin (Nord), France.

TENDERS RECEIVED AND ACCEPTED.

The *Bournemouth* Corporation have received the following tenders and schemes in connection with the requirements recently advertised. Mr. F. W. Lacey, M.Inst.C.E, is borough engineer and surveyor:—

1. For the supply and fixing of a steam pump, donkey pump and surface condenser:—

Goddard, Massey and Warner (simple condensing engine) (*accepted*)	£515
Ditto (compound condensing plant)	1,027
Worthington Pumping Engine Co. (compound condensing)	648
Ditto (triple expansion condensing)	698
Pulsometer Engineering Co. (compound condensing)	580
Tangyes, Limited (simple condensing)	530

2. For forced draught to existing boilers at Bournemouth pumping station:—

Goddard, Massey and Warner (*accepted*) £120 10

3. For the supply of steel masts for arc lamps for the square and pier approach:—

	⅝in. metal, each.	½in. metal, each.
John Spencer, Limited (*accepted*)	£120	£130
McDowall, Steven and Co. (Limited)	230	245

The *Rathmines and Rathgar* (*Dublin*) Township Commissioners, on the recommendation of the consulting engineer (Mr. R. Hammond), have accepted the following tenders for the plant for the township electricity works:—

Boiler House Plant (three 30ft. by 80ft. Lancashire boilers and accessories, mechanical stokers, feed pumps, injector, economiser, electric motor).—R. Taylor and Sons, £2,924.

Engine House Plant (one 300 kw. and one 150 kw. high-speed steam dynamos, and accessories, motor transformer, spare parts, &c.)—Mather and Platt, £6,386.

Crane (10 ton overhead travelling crane).—Higginbotton and Mannock, £264.

Switchboard and Instruments.—James White, £1,181.

Accumulators.—Tudor Accumulator Co., £1,958.

Underground Work (trenching, cables, &c.).—British Insulated Wire Co., £14,123.

Meters.—S. Z. de Ferranti (Limited), £500.

Messrs. Gray and Palmer's tender for wiring the jetty shelters, at *Gt. Yarmouth*, for £29. 12s. has been accepted by the Town Council.

The *Tunbridge Wells* Town Council have accepted the tender of Mr. T. Ashby Wood, for wiring the new offices of the electrical engineer, sanitary inspector, &c., at £21. 12s.

The *Winchester* Guardians have accepted the tender of Messrs. Dicks and Son for wiring the workhouse, for £166. There will be 162 lights, and current is to be taken from the mains of the local electric light company.

The Electricity committee of the Hull Corporation have accepted the tenders of Messrs. Thomas Parker (Limited) for the supply and erection of switchboards, transformers and motor generator at £3,350, and that of Messrs. Siemens Bros. and Co. (Limited) for cables, &c., at £10,654. 16s. The contract for the supply of condensers and steam, water and exhaust pipes has been given to Messrs. Barker and Aspey, at £915. 15s. 4d. All the contracts are in connection with the East Hull extension. Orders for the supply of a 750 I.H.P. steam engine and a 450 kilowatt dynamo have been placed with Messrs. W. H. Allen, Son and Co. and Thomas Parker (Limited) respectively.

APPOINTMENTS VACANT AND FILLED.

A technical instructor is required for the Thomason Engineering College, Roorkee, India. Further particulars are given in our advertisement columns, and applications must be sent in, on forms to be obtained from the Director-General of Stores, India Office, Whitehall, London, S.W., not later than 28th inst.

The Vestry of St. Mary, Newington, London, require a resident electrical engineer to take charge, under the superintendence of the consulting engineers (Messrs. Kincaid, Waller and Manville), of the erection of the machinery at their electricity generating station. Salary £250 per annum. Further information is given in an advertisement in another part of the present issue, and applications must be sent to the clerk (Mr. L. J. Dunham), Vestry Hall, Walworth-road, S.E., by Friday, Dec. 2.

The Holborn Guardians require an engineer capable of managing an electric lighting installation, steam laundry machinery, &c. Salary, £2. 5s. per week. Further particulars are given in an advertisement elsewhere, and applications, on forms to be obtained from the Master of the Workhouse, Shepherdess-walk, City-road, N., must be sent in by Wednesday, 23rd inst.

Mr. F. G. Holden, B.A., has been appointed resident engineer to the Scarborough Electric Supply Co. (Limited). There were 51 applicants. Mr. Holden, since serving his time with Messrs. C. A. Parsons and Co., has been four years with the Cambridge Electric Supply Co., as first improver and subsequently as assistant general manager. Mr. E. P. Harvey, B.A., has been appointed to the vacancy on the Cambridge staff.

Mr. E. E. Hoadley, chief assistant engineer at the Worcester Corporation electricity works, has been selected out of some 70 applicants for the post of electrical engineer to the Barking (Essex) Urban District Council. Mr. Hoadley has previously held appointments at the electricity supply stations at Islington (London), Eastbourne and Chatham.

Mr. Charles Stanley May has been appointed assistant-engineer at the new electric light station, Gibraltar. Mr. May served his apprenticeship with Messrs. Davey, Paxman and Co., at Colchester.

Mr. S. E. Sanders, of Ealing, has been appointed assistant engineer at the Bedford electricity supply station.

BUSINESS NOTICES.

Mr. John S. Raworth notifies that his address for professional purposes is now 2, Queen Anne's-gate, Westminster, S.W., and that his telephone numbers are 678 Westminster and 16 Streatham.

Mr. James Swinburne, consulting engineer, has removed from 66, Victoria-street, to Grosvenor Mansions, 82, Victoria-street, London, S.W. (Telephone No. 292 Westminster.)

The Blackman Ventilating Co., in consequence of their increasing business in the Midlands and the West, have opened new showrooms and offices at 1, Colonade-passage, Birmingham.

In consequence of increase of business it has been necessary to extend the premises of Messrs. Cox Walkers, electrical engineers, Darlington. The works at Feethams and Houndgate are being reconstructed.

The partnership of Messrs. Höfler, Raum and Co., art metal workers and designers, 18, Berners-street, London, W., has been dissolved so far as regards Mr. Wm. Höfler.

Messrs. Mosses and Mitchell, of 68-71, Chiswell-street, London, E.C., desire us to state that they are now connected with the National Company's telephone system, their number being 437, London-wall.

BANKRUPTCIES, LIQUIDATIONS, &c.

The petition presented by the Sussmann Electric Miners' Lamp Co. (Limited) for the winding up of the Electric Exploitation Co. (Limited) will be heard at the High Court on 23rd inst.

A petition has been presented by Messrs. Lander and Larsson for the compulsory winding up of the United Ordnance and Engineering Co. (Limited), and will be heard at the High Court on 23rd inst.

The final meeting of the shareholders of the Morecambe Electric Light and Power Co. (Limited) was recently held. The report of the liquidator showed that the gross assets had realised £3,423. 5s. 7d., the bulk of which had gone in payment of debenture bonds and interest, and the rest in law costs, rents and wages. No assets were available for either unsecured creditors or Ordinary shareholders.

Claims against E. W. Mayner and F. J. Hanford (trading as Mayner, Handford and Co.), electrical engineers, &c., 42 and 44,

Digitized by Google

James-street, Westminster, and Brighton Works, Redhill, are to be in by 30th inst. Mr. R. J. Ward, 2, Clement's-inn, London, W.C., is trustee.

It has been resolved to wind up Dutton and Co. (Limited) voluntarily for the purpose of reconstruction, and Mr. G. W. Bull, Worcester, has been appointed liquidator. Any claims against the company should reach Mr. Bull by Dec. 31. Particulars of the registration of the new company were given in our last issue.

The first meeting of creditors in the failure of Claude Vautin, electro chemist and metallurgist, late of 3, Upper Hamilton-terrace, St. John's Wood, N.W., and 66, Old Broad-street, E.C., was held on Friday last at the Bankruptcy Court, Carey-street, London. Mr. J. J. Saffery, C.A., 14, Old Jewry, E.C., was appointed trustee. The liabilities are given at £69,785. 14s. 10d. approximately.

Mr. R. Charubin, of 110, Cannon-street, London, E.C., has been appointed receiver and manager of the Mannesmann Tube Co. (Limited and Reduced). The appointment was made by order of Mr. Justice Stirling on behalf of the debenture holders, and Mr. Charubin will in future conduct the business of the company on their behalf. Future communications for the company should be addressed to 110, Cannon-street, and not to Landore.

Personal.—Mr. H. G. Barnett has joined the staff of Mr. Lloyd Wise, chartered patent agent, as technical electrical assistant.

Plant for Sale.—As announced in our advertisement columns, Mr. Wooller Jennings, 66, Thornton-road, Bradford, and George-street, Halifax, will sell by auction on Monday, the 21st inst., at 11 a.m., the whole of the machinery, utensils, stock-in-trade and effects of an electrical contractor's plant. Catalogues may be had of the auctioneer, and the plant may be seen four days prior to the sale.

"Sunbeam" Lamps.—A well got-up catalogue is issued by the Sunbeam Lamp Co., of Gateshead-on-Tyne, and 50, Fenchurch-street, London, E.C., in which many types of the Sunbeam Lamp are illustrated, described and priced. Tabulated particulars relating to all sizes and voltages of these lamps are given. Copies of the catalogue can be obtained free by post.

Watch Making Record.—In 1884 there was established at Kew an observatory for the examination and verification of scientific instruments with a special reference to watches. As evidence that the public have recognised the value of this important step, there is a large and increasing number of watches submitted to Kew, and a steady and marked improvement in the quality of the watches now offered to the public by the leading makers. In 1885, 110 watches out of 302 submitted for Class A, passed the test, while in 1897 out of 680 submitted, 492 passed. Competition for supremacy amongst the great firms became very keen after 1884, and this led to the institution of a system of calculation of merit, and a maximum of 100 marks was awarded: 40 for absence of variation from correct time of the watch while in various positions, 20 for absence of variation in changes of temperature from 40°F. to 90°F., and 40 for absence of variation of daily rate while in changes of position and temperature. The highest possible would consequently mean that no deviation from correct time was observed. Any watch performing within a limit prescribed by the Observatory authorities is classed "A," and for superior merit is awarded marks up to 80, and on obtaining this number is classed "A, especially good." Messrs. S. Smith and Son, of 9, Strand, London, have from the first been most successful in these tests, and in 1884 submitted a watch obtaining this highest distinction. From that time to the present strenuous efforts have been made to surpass this achievement, and after 14 years of incessant work, Messrs. Smith and Son have this month submitted a watch for test which has secured the extraordinarily high number of 88·1 marks. The watch is a gold, keyless, all-English chronometer, and the award establishes a record for English pocket chronometers. It can be seen at 9, Strand, and we are authorised to state that the mechanism of this watch and other watches of its class, will be willingly explained to those interested in the subject. In *The Electrician* for July 8th. we decribed the revolving escapement designed by this firm, and it is to the accurate measurement of time by this ingenious device that Messrs. Smith and Son attribute the high excellence obtained with their watches. It is felt, and reasonably so, that this success establishes a great advance in English horological science, and aids materially in elevating the English watch trade, which, although it has lost a large proportion of the demand for cheap watches, more than holds its own in watch movements of the highest class. A copy of a handsome catalogue of all-English watches, &c., will be supplied by Messrs. S. Smith and Son free of charge.

"Buffalo" Automatic Injector.—We have received from Messrs. Green and Boulding their latest catalogue of injectors, ejectors, metallic packings, boiler tubes, scrapers, air exhausters, &c.

Electric Fittings Catalogue.—Messrs. Jas. Guthrie and Co., 9, Leather-lane, Holborn, E.C., forward a catalogue of electric fittings in hammered iron, copper, and plain polished and scratched brass.

Engineers' Diary.—We have received from the *Indian and Eastern Engineer* a useful diary for 1899. The diary contains a mass of statistical information useful to engineers, and is a reference book upon many subjects. It is well printed and forms a useful desk companion.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Nov. 9 to Nov. 15, with the ports of destination:—

Australasia—Brisbane, £40; Canterbury, £24; Freemantle, £678: Melbourne, £143; Perth, £38; Sydney, £2,461; Wellington, £361. *Belgium*—Brussels, £110; Ostend, £45. *Brazil*—Rio Janeiro, £853 (including £808 telegraph material). *British Guiana*—Demerara, £25. *Canada*—Santos, £68. *Canary Islands*—Las Palmas, £15. *Ceylon*—Colombo, £33. *Chili*—Boca, £37. *Denmark*—Copenhagen, £70. *Egypt*—Alexandria, £120. *France*—Boulogne, £39. *Germany*—Hamburg, £120. *Holland*—Amsterdam, £210; Flushing, £10. *Hong Kong*—£1,737. *India*—Calcutta, £111. *Italy*—Naples, £13. *Japan*—Moji, £1,700: Yokohama, £1,290. *Madeira*—£12. *Norway*—Christiana, £406 (including £391 telegraph cable). *Russia*—St. Petersburg, £358 (including £103 telegraph material). *South Africa*—Cape Town, £141; Durban, £107; Port Elizabeth, £410. *Spain*—Santander, £20. *Sweden*—Gothenburg, £40. *Uruguay*—Monte Video, £27. *West Indies*—Trinidad, £26. Total, £11,898 against £8,922 in the corresponding week last year (Nov. 10 to Nov. 16).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Bangor (Ireland).—The Drake and Gorham Electric Power and Traction Co. have brought forward a proposal for the construction of an electric tramway between Bangor and Donaghadee.

Basingstoke.—The four applications recently received by the District Council for consent to a provisional order have been refused, and the Council itself will apply for powers.

Bradford Tramway Disaster.—Major Cardew has reported to the Board of Trade upon the recent fatal tramway accident which occurred on the Great Horton section of the Bradford tramways on Sept. 19 last. The report states that the Great Horton section is a new line recently equipped for electrical working. It is 2·8 miles in length, partly single and partly double line, with passing places and a continuous ascent, the average gradient being 1 in 24·16, the steepest 1 in 14·24. There are two sharp curves, one of 50ft. radius (where the accident occurred) and one of 46ft. radius. This line was inspected on behalf of the Board of Trade on Aug. 23, 1898, by Major Cardew, and in his report on that occasion attention was called to the steep gradients and sharp curves, and the necessity of an efficient brake power being provided. Major Cardew also advised that the trailer cars should not be used on this section, but to this the Bradford Corporation objected, and the formal certificate of the Board of Trade for the working of the line has not (says Major Cardew's report under review) yet been granted. The report states that the accident occurred to reserve car No. 16 on the driver's first down journey that day, and the rails were greasy or slippery at the time. The driver had been a conductor on the steam trams, and commenced driving the electric car on Aug. 29 last, and had acted as driver a fortnight before the accident; the trolley pole was disconnected from the wires before the accident, and the hand-brake was found hard on the wheels badly flatted, and the electric brake not applied. So much was established by undisputed evidence. Conflicting evidence was given as to the usual speed of the cars, and the driver's statement was to the effect that before he lost control the cars had a speed of five miles per hour. Evidence on the subject of the position of the reversing lever and the controller was given by two electrical engineers well acquainted with electrical equipment of the car, who declared positively that the lever was at the "reversed" position, while the tramway manager, whose evidence was supported by the driver of the car, asserted that it was "forward." It is pointed out that this matter is of some importance, because if the lever was at the "reversed" position the electric brake would be inoperative. A very important question (the report continues) was raised as to the sufficiency of the brake-power provided on this line of tramway, and certain tests were carried out by an expert. In these tests two cars were coupled together, and were allowed to run freely for a distance of 72 yards down a gradient of 1 in 14·24. They were then stopped by the application of brake-power on one car only in distances, from the point of application, of 91 yards for the hand-brake kept on, 70 yards for the hand-brake applied intermittently, and 68 yards for the electric brake. Afterwards similar experiments were made with one car alone, when the hand-brake brought the car to a standstill in 36yds. 1ft., and the electric and hand-brake in combination in a distance of 25yds. 1ft., and at a second test of 21yds. 1ft. The car was

Digitized by Google

afterwards run down the gradient under control, the electric brake being used on the second point of adjustment, which is what the drivers have been instructed to use, and was stopped in nine yards. These tests appear to Major Cardew to indicate very efficient brake power. Under the conditions the car must have acquired a velocity of about 20 miles an hour, and to stop it on the incline in 21yds. 1ft. requires a force of nearly one-quarter of the whole weight, applied in the opposite direction to the motion. This, he considers, about the maximum retarding force that can be expected from any braking arrangement which depends upon friction between the wheels and the rails. Later a slipper-brake test was made under similar conditions to the above, the results being as follows :—Car allowed to run free on grade of 1 in 14·24 for a distance of 72yds. was then stopped—

By slipper-brake alone in		178½yds.
By hand	ditto	64½yds.
By electric	ditto	37yds.

The car allowed to travel down the grade with electric brake on at second point stopped in about half its length, or, say, five yards. From these tests it appears that the slipper-brake alone, as now fitted, is the least effective of all as an emergency brake, to some extent due to the flat pitch of the screw by which the brake is applied ; but, considering the small fraction of the whole weight of the car that can be possibly brought to bear upon this brake, Major Cardew doubts greatly whether it can be made as effective an emergency brake as the other brakes which act upon all the wheels, and which, therefore, bring into play as a retarding force a friction due to the whole weight of the car. It has, however, an advantage in that it applies a surface of wood to the steel rail, the co-efficient of friction between wood and iron or steel being generally greater than that between iron and iron. The fact is that if a car be allowed to acquire such a speed as 20 miles an hour on a steep gradient, no brake acting by friction on the running rails will stop it in a distance that could be considered safe. There appears to be an impression that a slipper-brake is quite without influence upon the wheel brakes. This is not the case ; whatever proportion of the weight of the car is utilised for the slipper-brake must be lost for the wheel brake, and it will be found that the wheels skid more easily on the application of the hand-brake if the slipper-brake be pressed down. Moreover, to the extent to which the slipper-brake relieves the weight on the wheels it tends to increase the risk of the wheels leaving the rails at curves and facing points. The real advantages of the slipper-brake appear to be found in the use of a block of wood pressing on the rails, whereby a greater co-efficient of friction is secured, and the destructive action inseparable from the dissipation of energy by means of friction is to a great extent concentrated upon a cheap and easily replaceable fitting. The addition of this brake to those already provided also adds one more to the method of retardation available. There are, however, three methods available without it, viz., the hand-brake, the electric brake, and the reversal of the motors. Finally, Major Cardew is of opinion that the accident was due to the following causes :—

1. That the cars were not run within the limit of speed of not exceeding six miles an hour on the down journey.

2. The unfortunate combination of a driver with very little experience ; a conductor with none at all, but with a little knowledge which is proverbially a dangerous thing ; a slippery road ; and extra pressure on the traffic, the driver certainly used the brake power provided in an injudicious manner. The conductor put on the hand brake, and thus deprived the driver of the full control of the brake power ; and he also caused the trolley to be disconnected, thus depriving the driver of the power of reversing, which might have prevented the accident. The brake-power was ample, and by means of the graduation of the electric brake the speed can be regulated with ease and certainty, provided that a speed of six miles an hour be not exceeded. He approves of the addition of a slipper brake—not, however, as an emergency brake, but as a brake to be continuously in use, since by it also exact regulation of speed can be obtained, and its use diminishes the strain on the motors and the excessive wear of the wheels.

He adheres to the opinions expressed in his report of inspection that the speed on the down journey should not at any point exceed six miles an hour, and that trailer cars should not be allowed on this line, and, if the requirements of that report are complied with, he recommends that the line should be certified by the Board of Trade as fit for traffic.

Under the Council's proposed tramway bill lines are to be constructed to Clayton and Queensbury, and from Foster-square along Kirkgate to Whetley Hill and Toller-lane.

Bristol.—Mr. Geo. Pearson has been re-elected chairman of the Electrical committee for the ensuing year. At the last meeting of the committee it was explained that the whole of the plant required for the extensions at Temple Back had not yet been obtained, and that further machinery would be needed to meet the increased demand for electric current. The number of customers to date was 893. The equivalent number of 8-c.p. incandescent lamps applied for was 66,027. The number of customers actually connected was 870, with a total of 59,689 lamps.

Calcutta.—The negotiations between the Corporation and the Calcutta Tramways Co. regarding the introduction of electric traction are at a standstill, as the Company refuse to accept the Corporation's conditions as to length of lease and ultimate purchase of the undertaking.

Canterbury.—The question of extensions to the electric lighting plant and mains has already been forced upon the Town Council, although they will not be in a position to supply current before January. At the last meeting the Electric Lighting committee submitted a report from Mr. R. Hammond recommending the expenditure of a further £8,000 in extensions. The chairman (Ald. Mason), however, explained that, owing to the increased demand for current, the original extension scheme was deemed insufficient, and Mr. Hammond has been instructed to submit a more comprehensive scheme which would entail an expenditure of about £12,000.

Chelsea (London).—The Vestry has instructed Mr. Sydney Morse to make application on its behalf for a provisional order for the Kensal Town portion of the parish.

Colchester.—The official opening of the electricity supply works is to take place the first week in December. Orders are in hand for an equivalent of about 2,000 8-c.p. lamps.

Colwyn Bay.—The electric lighting of the promenade has been discontinued until next season. A public meeting is to be held to consider the advisability of putting down plant for the permanent lighting of the streets.

Crewe.—Messrs. Hopkinson and Talbot, successors to the consulting business of the late Dr. J. Hopkinson, have been retained as consulting engineers by the Town Council in connection with their proposed electric lighting scheme.

Dudley-Sedgley Tramways.—The British Electric Traction Co. took over the control of these tramways on Friday last. It is proposed to reconstruct and equip the lines electrically as promptly as possible. The Company are applying to the Light Railway Commissioners for an order to lay down connecting tramlines to effect a junction with the Dudley and Stourbridge line. In the event of no unreasonable obstacles being put in the way by the Dudley, Sedgley, Coseley, or Wolverhampton local authorities, the Company propose to push forward the work of reconstruction without waiting for the order from the Commissioners to be issued.

Electric Power Plant.—In the new machinery sheds at the yards of Sir James Laing and Sons, Sunderland, electric motors are employed for driving the machinery.

Electric Traction Notices.—The Devonport and Dundee Corporations notify that they intend to apply for powers to construct and lease tramways and to employ mechanical traction.

Exhibition.—A motor car exhibition is, it is reported, to be held at the Agricultural Hall, London, from July 3 to 15.

Finchley (Middlesex).—The District Council will apply for a provisional order.

Fraud.—At the Devon assizes Mr. Justice Kennedy sentenced Ernest John Thomas, electrical engineer, to twelve months' hard labour for obtaining credit from various electrical and engineering firms by means of false pretences and fraud.

Glasgow.—At the meeting of the Tramways committee, on Wednesday, the manager (Mr. John Young) presented a report on the results of the recently-inaugurated Springburn-Mitchell-street electric tramway. He stated that during the past fortnight the working cost per car mile was 6½d., while the receipts were 1s.4½d., leaving a margin of 8d. to meet interest on capital. That result had been secured, notwithstanding the fact that they had not yet had the full use of the engines. He estimated that to convert the 28 miles of lines in the city to the conduit system of electric haulage would cost £347,000 more than to equip them on the overhead system. At the same time, the saving as compared with horse traction would be considerable. He estimated that the underground system would cost 5½d. and the overhead 5d. per car mile. Nine miles of rails would not require to be altered, but the remainder, which were laid on the old shallow pattern, would have to be replaced. The committee resolved to withdraw the recommendation to construct the overhead system *via* High-street to Govanhill, and to consider whether part of the route might not be utilised for an experiment with the conduit system.

Government Office Lighting.—The electric lighting at the Colonial Office, Downing-street, S.W., has been completed.

Great Yarmouth.—The Town Council are seeking powers to construct electric tramways to Gorleston and Southdown.

Guayacan (Chili).—A small private electric lighting installation exists at the smelting works in Guayacan, near Coquimbo, and there is also an isolated installation at a large dairy farm in the same vicinity. There are, however, no persons or firms engaged in electrical construction work in this part of the west coast of South America.

Digitized by Google

Heckmondwike.—The Board of Trade notification has been given to the District Council that the period of the provisional order has expired.

Hull.—The Corporation are committed to the following expenditure during the next two years:—Electric lighting, £90,000; electric lighting for East district (powers applied for). £26,000; electric tramways, &c. (estimated), £300,000; technical schools, about £18,000.

Ilkeston.—The District Council have decided to establish electricity supply works and to construct a system of electric tramways in the town, at an estimated cost of £80,000. Provisional orders are being applied for.

Islington (London).—The Vestry objects to the proposal of the National Company for placing their wires underground. The company are, therefore, applying to the County Council for permission to retain certain overhead wires in Islington with spans exceeding the length allowed under the London Overhead Wires Act. If this permission is withheld it is stated that one of the exchanges will have to be closed.

Italian Machinery Industry.—An article in the *Italia*, published at Rome, reviews the Italian machinery industry, which during the past 15 years has developed to a remarkable extent. Whereas in the early 80's Italy obtained her engines, boilers and iron and steel supplies from abroad, she is now able to provide for all her ordinary requirements by home manufactures, including naval and railway construction. In the latter department considerable exports of locomotives are made. Development is, however, most marked in connection with electric machinery and apparatus, which is now exported in large quantities, not only to the South American markets, but to European countries, including England.

Japan.—A Chicago correspondent reports that the Siemens and Halske Electric Co., of America, is negotiating with the Japanese Government to form in Chicago a syndicate, with a capitalisation of about $10,000,000, to install and operate the electric street car lines and electric light and power plants to be established in Japan, but especially in the towns of Tokyo, Yokohama, Nagasaki and Osaka. A limited liability company, which has obtained a monopoly of the trolley-trams, is about to be promoted at New York.

Kingswood (Bristol).—The District Council will apply for sanction to borrow £2,100 for electric lighting purposes.

Leeds.—The City Council will promote a bill for the construction of a tramway to the boundary of Bradford, to be equipped electrically.

Leigh (Lancs.).—The District Council have received the sanction of the Local Government Board to borrow £10,216 for the establishment of electricity supply works.

Leith.—The burgh electrical engineer (Mr. W. A. Bryson) has been asked to report, in the event of electric traction being adopted on the Leith tramways, and the Edinburgh Corporation continuing to use the cable system, what mechanical arrangements are practicable to admit of the interchange of traffic from the mutual boundary at Pilrig, so as to obviate changing carriages there, and also to report on the method of crossing the harbour by the new swing bridge.

Light Railways.—Notice is given that an application is to be made to the Light Railway Commissioners by Mr. B. M. Kilby for an order to construct a light railway from Blyton to Frodingham (Lincs.)

The Camborne District Council have conditionally approved the proposal to construct a light electric railway between Camborne and Redruth.

The Llandudno District Council will oppose the confirmation of the order granted to the Llandudno and Colwyn Bay Light Railway Co. for the construction of a light (electric) railway in the Llandudno district.

London County Council.—The Council have at last consented to the application of the National Telephone Co. for the erection of new offices on the Victoria Embankment.

We refer elsewhere to the deadlock at Islington owing to the National Company being unable to place its wires underground, and, at its last meeting, the County Council discussed this question. The Highways committee now recommend that permission be granted for the retention of certain overhead wires, the spans of which exceed the length allowed by the London Overhead Wires Act. The recommendation, however, was opposed, and the matter stands over for a week.

Manchester.—Ald. Higginbottom has been re-elected chairman of the Electricity committee. At the meeting of the City Council on Wednesday a report from the committee was presented on the introduction of electric traction on the local tramways. Ald. Higginbottom held that the committee were justified in adopting the overhead trolley system. They had to take into consideration the local condition of the streets and the state of the rails, as well as the capital cost of the overhead and conduit systems, their efficiency and working cost. There were 67 miles of tramway track in the city. The rails weighed 96lb. per yard, and were quite suitable for electric traction. Nothing was required to be done except the bonding, which was already being done, at a cost of £135 per mile. They would have, in addition, to renew the crossings with steel crossings, and this work was being done by the committee without any interruption of the traffic. The capital cost of the undertaking, if the overhead system were adopted, would be about £600,000, and Ald. Higginbottom was of opinion that within a few years of the tramcars beginning to run electrically there would be a net annual profit in aid of the rates of about £70,000. If the conduit system were adopted and the extra capital expenditure of £629,807 incurred, the interest and sinking fund alone on this extra capital would be about £38,000, and the net profit would therefore be reduced by this amount. There were two important points to be considered, viz., the efficiency and working cost of the two systems. The difference was ½d. per car mile in favour of the overhead system. The report was adopted.

Merthyr.—The District Council have decided to sanction the British Electric Traction Co.'s application for electric lighting powers, provided the Company include in their proposed order the whole parish of Merthyr; that at first and within two years of obtaining the order they should lay mains to light the district within half-a-mile of their proposed tramway, and that within three years they should lay mains to any portion of the parish as required by the Council; the price to be charged for current not to exceed 4d. per unit.

Musselburgh.—A committee, with power to consult an electrical expert, has been formed to consider the question of establishing municipal electricity supply works.

Nationalisation of the Telephones.—Mr. Edward Rae, writing from Liverpool and expressing the views of the Council of Associated Stock Exchanges, advocates the nationalisation of the telephones. Mr. Rae thinks

"it is clear that the attitude adopted by the Post Office towards the National Telephone Co. will have one effect—that is, the prohibition of that development on the part of the company which ought to meet the growing and imperative demands for its services. It is scarcely possible to expect a threatened company to embark fresh capital in order to meet such requirements. On the other hand, any attempt at a Government local service in competition with the National Company might easily result in a disastrous loss to the Post Office. . . . . Assuming a Government purchase based upon the average market prices, high and low, of the company's stock and shares during the past three years, taking into consideration the reduced interest, charges and economy of working, and crediting the business with nothing beyond its normal progressive development, the result, so far as I can estimate it, would be that the surplus profits and royalties, if placed to a cumulative sinking fund, would at the expiry of the licence (13 years hence) practically suffice to extinguish the purchase money. Surely this would satisfy the most prudent Chancellor of the Exchequer. The adoption by the Government of the National Company's system and its prompt development under the guidance and co-operation of the Company's present administration offer, in my judgment, the only assurance of a widespread and perfect system of telephones for the present generation of business men."

Newington (London).—The Vestry has decided to at once take up the first instalment (£10,000) of the electric lighting loan of £50,000 granted by the London County Council.

Norway.—India-rubber vessels for galvanic materials are admitted free of duty under the modifications of the Norwegian Customs tariff, to come into effect from April 1 next. A duty of 2d. per kilo is proposed on motor carriages.

Paddington (London).—The Vestry have been asked by the Metropolitan Electric Supply Co. to put in writing their proposals with regard to the purchase of that portion of the Metropolitan Co.'s undertaking which serves the Paddington district. This request was discussed at the last meeting of the Vestry, but there seemed a difference of opinion as to the course adopted by the Electric Lighting committee. One member asked whether it would not be advisable to have an expert's assistance in the negotiations but the chairman of the committee did not consider such a course necessary.

Paisley.—The electricity works will be opened early in January.

Poplar (London).—A communication from the Board of Trade notifying that the time had arrived for them to consider whether the Poplar provisional order should be revoked has been referred to the Electric Lighting committee.

Provisional Order Notices.—Official notice of intention to apply for provisional orders has been given by the following:—Bethnal Green (St. Matthew) Vestry and the Lewisham District Board of Works (London); the Glossop, Ilkeston, Keighley, Newcastle-under-Lyme, Ryde and Wednesbury Corporations; the Brentford, Castleford, Darfield, Erith, Mexborough, Mirfield, Teignmouth and Winsford District Councils, the Inverness Police Commissioners; the Electric Works Co. for Walton-on-Thames and Weybridge and the Kelvinside Electricity Co. for Partick.

Ramsey.—The Isle of Man Tramways and Electric Power Co. and the local gas company have been invited to submit tenders for the better lighting of the promenades.

Digitized by Google

Reading.—Power is being sought by the District Council to construct additional tramways in the town and to introduce electric traction on the entire system.

Rochdale.—During the coming year electricity supply works are to to be inaugurated, the tramways taken over, and other municipal improvements carried out.

Salford.—In the bill promoted by the Salford Corporation power is being sought to construct and work additional tramways and to introduce electric traction.

Shanghai.—We would draw our readers' special attention to two announcements of the Shanghai Municipal Council which appear in our advertisement columns this week.

Shoreditch (London).—At Tuesday's meeting the Lighting committee submitted the accounts of the electric light undertaking and refuse destructor works for the complete year to June 24. The total income from sale of current for the period amounts to £8,254. 2s. 1d., "sale of current to dust destructor" is put at £536. 5s. 8d., miscellaneous receipts £120. 4s. 7d., and "sale of stores to other departments" £130. 8s. 4d., making the total credit £9,041. 0s. 8d. Debits amount to £3,214. 14s. 7d., interest and redemption £2,641. 16s. 2d., leaving a net balance or surplus for the year of £3,184. 9s. 11d. The committee express their satisfaction at the result, especially as it has been obtained in the face of a loss of £500 during the first quarter of the year. The amount set aside for interest and redemption is stated to be more than sufficient to provide for depreciation of the undertaking. The dust destructor accounts show a debit balance of £1,758, which the Committee state is represented by steam used in the lighting station and library. If the debit balance is charged against the surplus of the electricity works the result would be as under :—

Credit balance on electricity undertaking	£3,184	9	11
Add saving on previous expenditure of barging refuse	1,253	5	1
	4,437	15	0
Deduct debit balance on destructor	1,758	14	6
Net profit and saving...	£2,679	0	6

Mr. H. E. Kershaw moved the adoption of the report, which Mr. Hodder, although believing that the lighting scheme was bound ultimately to succeed, opposed, and Mr. Hodder's views were supported by Mr. Freeman and others, Mr. Winkler expressing the view that the Vestry had been bamboozled by persons who desired to make a name for themselves. Mr. Kershaw took exception to this statement and replied generally to the remarks made by previous speakers. Ultimately it was agreed by 30 votes to 11 to receive the report, and to refer it back to the committee to allocate the disposal of the profits.

Slough.—An electrical expert is to be engaged to prepare a report as to establishing electricity supply works.

Stretford.—The District Council propose to acquire so much of the undertaking of the Manchester Carriage and Tramways Co. as lies within the district of the Stretford Council. Mr. R. P. Wilson: of Westminster, has been engaged as consulting engineer at a fee of 40 guineas to prepare an electric lighting scheme for the district.

St. Anne's (Lancs.).—The District Council has decided to establish municipal electricity works.

St. Pancras (London).—A curious state of affairs has arisen in relation to the supply of electric current in one of the main thoroughfares in this district—Brecknock-road. It appears that the houses in this road are in St. Pancras, whilst the roadway is under the control of the Islington Vestry. The electric lighting department of St. Pancras is consequently unable to lay a main for supplying current to the houses in question. The Board of Trade are to be asked for sanction to erect overhead wires for the purpose.

Sunderland.—The Town Council have resolved to promote a bill for powers to take over and work the tramways, to introduce electric traction, and to extend the electric lighting system.

Telephone Municipalisation.—The Edinburgh Town Council have decided to make application for a telephone licence and to obtain powers to establish a telephone exchange system.

It is currently stated that in view of the proposed action of the Government next session, in dealing with the report of the Telephone Select Committee, the Manchester Corporation will not proceed further with the clauses of its new General Powers Bill which relate to the establishment of a local exchange under licence from the Postmaster-General.

Tobermory (N.B.).—Mr. R. F. Yorke explained his scheme for the electric lighting of this district to a meeting of ratepayers last week. Water power is to be used, and in the event of the scheme being carried out by the Burgh Commissioners, the Laird of Aros offers to give water rights free of charge. The total outlay entailed by the scheme is put at about £2,000.

Tramway Traction.—Mr. J. Allen Baker forwards a copy of an article from the current issue of an American journal on the subject of "Comparative Costs and Profits of Cable, Electric Conduit and Horse Tramways in New York City." Mr. Baker calls attention to what he describes as "the remarkable figures given as the result of a year's working of the Metropolitan Street Railway Co, of New York," and he claims that these figures fully comfirm his recommendation of the electric conduit system of traction for the district controlled by the London County Council. Mr. Baker says: "An economy in operating that I believe has never been equalled by trolley or any other system is now proved in New York, and, no doubt, London and other large cities in this country will profit by the lessons to be learned from our American cousins." The pamphlet under notice includes a transcript of the private costs sheets and other records of the Metropolitan Street Railway Co., by which it is stated a true comparison of the relative costs of cable, horse, and electric railway working, in a single city, under substantially the same conditions, is available. The Metropolitan Company's service deals with 250,000,000 passengers per annum.

Tunbridge Wells.—The Local Government Board have given their consent to the borrowing of a further sum of £15,000 for electric lighting purposes. The new offices of the electrical engineer are to be wired and put in telephonic communication with the Town Hall.

Vaynor and Penderyn (Glam.).—The British Electric Traction Co., which is about to construct a light (electric) railway between Merthyr, Dowlais and Cefn, has offered to supply electric current for public and private lighting in this district. The council are considering the offer.

Water Power Utilisation in the Highlands.—In the *Edinburgh Gazette* of the 15th inst. notice is given of intention to promote a bill next session for the incorporation of a company for utilising water power in the generation of electric current, and for the erection of stations at or near Loch Leven, in Inverness-shire.

Whitechapel (London).—The District Board of Works have decided to purchase Messrs. Ind, Coope and Co.'s premises in Osborn-street for £18,250, as a site for an electricity supply station.

Windsor Castle.—The Queen's private chapel has been wired and fitted for the electric light.

Works Lighting.—The cement works of Messrs. Martin, Earle and Co., at Wickham, Rochester, have been provided with electric lighting plant. Current is supplied to twelve 2,000 c.p. arcs and about 200 16 c.p. incandescents. The work of installation was carried out by Messrs. A. E. Bennett and Co.

Wrexham.—A London company has arranged to take over and electrically equip the Wrexham-Johnstown tramway from the Wrexham and District Tramway Co.

Electro-Harmonic Society.—A "ladies' night" entertainment will be given at the St. James's Hall, Regent-street, W., on Friday, Nov. 25, at 8 o'clock.

COMPANIES' MEETINGS AND REPORTS.

Western and Brazilian Telegraph Co. (Limited).

The thirty-sixth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on the 11th inst., under the presidency of Mr. W. S. ANDREWS.

The SECRETARY (Mr. E. Steer Hodson) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: At the corresponding period in 1897, when we met, I was obliged to lay on the black paint. It was about the very worst period that we had had to suffer under, and things were not at all wearing an appearance of cheerfulness. At the same time, although the accounts came out badly, we were enabled to feast you a little upon prospects—not always a satisfactory thing, unless they are real. We told you that the revenue was continuing to increase and that the expenses were continuing to diminish, and, therefore, you went away in a comparatively cheerful state of mind. I am pleased to say that our forecast in both those respects has turned out to be correct. The present accounts do show a great improvement over those of the corresponding period of the previous year. The receipts have continued to increase and the expenses have continued to diminish. The earnings, as a fact, exhibit a considerable improvement, having reached £72,692 as compared with £59,754, an increase of no less than £12,938; and in addition to this we are fortunate to have received over £10,000 from the Platino Company in the half-year against £11,000 in the whole of the year 1897. The expenses show a satisfactory diminution, as foreshadowed. They amount to £39,376 as compared with £44,575—a decrease of £5,199. The decrease is mainly under shipping, in spite of higher prices of coal and the ships being more at sea, the great point being that at the corresponding period last year we had a ship on hire, while in the period under review we had our own ship, which did the whole of the work. The other expenses show so little difference that it seems to me that I should be only wasting your time if I went into them, for there are a large number of items and the whole difference is only between £200 and £300. We bring down a balance, after deducting expenses, of £33,316. Adding the amount brought over last year, £1,428, and the Platino dividend of £10,169, we have a total of £44,914. From this balance we have to deduct debenture interest, £8,041; debenture stock redemption fund,

Digitized by Google

£1,078; amount added to reserve, £8,000; and income tax, £2,016, making altogether £19,136. This leaves us £25,777, and enables us to recommend a dividend of 5s. per share. This will require £24,349 and leave us with a balance of £1,428 to carry over for the benefit of the current half-year. Now, when you remember that in the corresponding period of last year we had to withdraw £7,500 from our reserve fund in order to enable us to declare a dividend of 3s. per share, whilst this half-year we pay 5s. per share and add £8,000 to the reserve fund, I think you will feel that on the whole it is not such a bad result, and I think it fully justifies the few expressions of a sanguine character which we ventured to indulge in in the corresponding period of last year. Gentlemen, you are aware that the requisite number of Western and Brazilian shares having been sent in for exchange for Brazilian Submarine shares, the agreement between the Companies has become operative. As you know—but I think it is necessary to emphasise it—this agreement is not for an amalgamation, but is confined to what promises to be a very successful effort to unify our interests. The independent organisation and working of the companies under their concessions, and with unimpaired privileges and obligations, remains identically the same, and in order to secure the objects we had in view—namely, the harmonious working of the undertakings for a common end, recourse has been had to similar measures to those adopted in the case of the Platino Co., with which you are all perfectly well acquainted, and which have worked so well—that is, an exchange of shares for those who cared to make it, unification of Boards to secure identity of action, and an executive acting under the direction of the Boards for all the companies. The objects of all this solicitude, besides the protection of the shareholders' property, were the employment of funds as and when required for the improvement of the systems under proper provisions, the unification of the working from end to end of the lines, and thus the establishment of a service calculated to prove adequate, progressive, and satisfactory alike to the Brazilian Government and people, as well as to all interested in telegraphic communications with the South American continent. The Directors, therefore, have been made interchangeable, and they have done me the honour to make me chairman of the Brazilian Submarine Co., partly, I suppose, on account of my grey hairs. Seniority is rather an unpleasant kind of claim, but sometimes it is brought forward. It is not proposed to appoint any managing director, but Mr. Axworthy has been made the joint manager of these concerns. The secretaries of the Brazilian Submarine Company and this Company have each of them retired after 25 years of service, and Mr. Hodson, an old servant in the traffic department of this Company, has been made joint secretary. Practically this comprises all the staff measures at home, and I am pleased to say that abroad the great abilities and long and able services of Mr. Reidy, who is our agent and representative out in Brazil, have been recognised by his having been appointed to the same position in the Brazilian Submarine Company that he has long held and fulfilled so satisfactorily with us. You see, in point of fact, that we have endeavoured to carry out one principle all the way through—to make as little alteration as we possibly could, and to identify as closely as we could the three Companies. It is rather early days, of course, but still we have now had some actual experience—not much, it is true—of the results that it was anticipated would accrue from the homogenity of management and working, and this experience encourages us in the opinion that we have made no mistake, and that our institutions working together will be able to secure the public advantages that have been so strong a motive with us all the way through. I do not want you to think that I am trying to persuade you that there is no selfish motive in all this. Of course, there is. We are selfish because we want to benefit you, but what we did for you is this—we felt that there is only one method by which we might bring about the best results—namely, that we must have the best lines; we must ensure promptitude and certainty, and these things, as a fact, there is, no doubt, do encourage the traffic. Every facility that might be prudently conferred leads to increased user, and the more the needs of the Government and of commerce are met, the more these respond, and the greater becomes the remunerative character of the results ensured. Therefore, we are selfish if you like, but at the same time you may call it, if you please, an enlightened selfishness. We only hope to get what we want—namely, the highest scale of remuneration for the shareholders by dint of something which we give pretty well broadcast to the Governments and the people, to whom we ensure, I believe, the largest benefit of this operation. There is practically nothing further to which I can draw attention profitably, and I will, therefore, propose the following resolution:—

"*That the Report and Accounts to 30th June last, now submitted, be and the same are hereby approved and adopted, and that a dividend of 5s. per ordinary share, or at the rate of £3. 6s. 8d. per cent. per annum, free of income tax, for the six months ended 30th June last, be and the same is hereby declared.*"

Lord RICHARD H. BROWNE seconded the motion.

Mr. GEORGE ENNIS, after congratulating the Directors of the two Companies on the way in which they had carried out the arrangement entered into between them, remarked that they were all exceedingly pleased at the appointment of Mr. Andrews as Chairman of the Brazilian Submarine Company. He must make one criticism on the accounts. He thought that the Directors had erred on the side of excessive generosity to the reserve fund. They already had a fund amounting to over £63,000, and the Board now proposed to add £8,000 additional. He thought that they would have been better advised and have been more in accord with the views of the shareholders if they had paid a dividend of 5s. 6d. instead of 5s. This would have given the deferred shareholders 1s. more, or nearly double the amount paid to them, and while doing this the Directors would have still had over £6,000 to transfer to the reserve fund. He was afraid that they were rather suffering from the Directors' anxiety to pile up the reserve fund.

Major COTTON said that they were all very grateful to the Directors for the way the arrangement between the two Companies had been carried out, but, as a large deferred shareholder, he thought that there was a great deal in what Mr. Ennis had said. He did not think that they had got all that they might have had, but that was in the past. He asked the solicitor of the Company whether it was in the power of the shareholders to increase the dividend recommended by the Directors. If it could be done he thought it would only be fair to give more to the deferred shareholders, who had borne the heat and burden of the day so long. The income tax had always been paid on the preferred shares by the Company, and it was a very moot point whether the Company should do this. The payment came out of the deferred shareholders' pockets. He regretted that the auditor was not present to answer this point, but he had called on him and knew his views, and he rather thought that the auditor was with him in the matter. As he had said, they all congratulated the Directors on the arrangement which had been carried through. He had been very glad to notice that the Directors had seen their way to make some recognition of the past services of Mr. Cunningham. He was also very glad that their traffic accountant had been appointed to the position mentioned by the Chairman.

The SOLICITOR stated that by Clause 133 of the Articles of Association no larger dividend could be declared than that recommended by the Directors, but a general meeting might, if they liked, declare a smaller dividend.

The CHAIRMAN: I may say that we have considered very carefully the amount of dividend that should be declared. We thought that we were proposing a very big rise on the dividend declared at the corresponding period of the previous year; but, of course, in matters such as this there is always a little give-and-take, and there are also considerations that have to be brought in as material. We saw that the Brazilian Submarine Co. added very largely to their reserve fund—very much more materially than we are proposing to do now. That, and other reasons, we believe, make our proposal very much in the interests of the shareholders. We thought that if we paid 5s. a share and added £8,000 to the reserve fund we should be doing a wise thing. I mention this because I do not want to justify myself by mere technicalities; I want to show the shareholders that we do consider these things, and that we do what we do because we believe we are right. He then put the motion, which was carried unanimously.

A SHAREHOLDER enquired whether it was proposed eventually to have a full amalgamation with the Brazilian Submarine Co.

The CHAIRMAN: We must be guided by circumstances. It would be premature to make any forecast now.

Mr. COLEMAN said that the Chairman had not touched on the question of the purchase of this Company's undertaking by the Brazilian Government. He thought that this matter had been referred to on one or two occasions by the Directors, and his object in attending the meeting that day, was to hear something about it. He gathered that there was an understanding, an arrangement, but not an amalgamation, with the Brazilian Submarine Co., but he desired to know in what position the Western and Brazilian Co. stood, with respect to the Brazilian Government. He had consented to carry on his interest in the Brazilian Submarine Co., in which he had also been a shareholder for some years, but if he had been under the impression that there was not going to be an amalgamation he might have continued his interest in the Western and Brazilian and the Brazilian Submarine Companies as heretofore.

Major COTTON enquired the number of shares or the percentage of shares that had been interchanged.

The CHAIRMAN: It is a large number, but I did not propose to go into that matter. The honorable proprietor (Mr. Coleman) says that on one or two occasions reference was made in our reports to proceedings taken by the Brazilian Government with respect to the purchase of this Company's line. I think it appeared not only on one or two occasions but on a good many more. The Brazilian Government, I take it, did at one time intend to purchase the line, and if they had had the money, I believe that they would have done so. There were great disturbances in Brazil, however, and the financial position of the country certainly did not encourage the Government to undertake large ventures of any sort. We continued in our reports to refer to the state of things in Brazil, but in the end we thought that that course was getting stale, and we gave it up. There did not appear to be any prospect of anything coming of it, and instead of that being done, we have done something else which should certainly be equally satisfactory to the shareholders, and do away with what might otherwise have been felt to a certain extent as a disappointment—that the purchase business had gone off. Then, I am asked, how does this arrangement affect the Government supposing that they still desire to purchase our line. My impression is that they will not, but supposing that they did the matter does not affect them. We go on, as I have said, with the same privileges and obligations, and the Government have, of course, precisely the same rights as they have had all the way through. That is the essence of this arrangement. Had we wished to do so we could not have interfered with the *status* of the Government with regard to ourselves, or of ourselves with regard to the Government. With respect to the shares, those who exchange their shares in this Company for shares in the Brazilian Submarine Co. do not remain shareholders in this Company, while those who retain their shares retain their membership and their interest in this concern. There is no other way of bringing about an arrangement of this sort. Nominally the amount of the capital remains the same. The Western and Brazilian Company still continue to have the same capital, and, if I may say so, still continue to have the same motives to endeavour to pay a good interest on it; but at the same time I feel bound to add that, although the Western Company's receipts do show, as you have all seen, a very satisfactory improvement, it so happens that our business is in such close relation that where we benefit 6d. in our concern, I should say that the Brazilian Submarine Company would benefit about 8d. There is, therefore, no reason why any shareholder in the Western Company should hesitate to exchange his shares, because if he does so he will see a still larger improvement in his property.

Digitized by Google

A SHAREHOLDER: If two-thirds or a half or a quarter of this capital is transferred to the Brazilian Submarine Company, how can the capital of this Company be the same?

The CHAIRMAN: The capital of the Company remains the same—it is only differently distributed. It is not the capital that is transferred, but only the certificates.

Mr. ENNIS said he thought it would be well if shareholders had any doubt on points such as this for them to address the secretary, who could explain them.

The CHAIRMAN: That is a very good suggestion.

The proceedings then terminated with a vote of thanks.

Cuba Submarine Telegraph Co. (Limited).

The report of the Directors of this Company for the half-year to June 30 last states that the total receipts amount to £33,504. 2s. 8d., and the gross expenditure to £8,091. 11s. 3d., leaving £25,412. 11s. 5d., which, added to £3,254. 8s. 11d., brought forward, leaves £28,667. 0s. 4d. to credit of revenue. The traffic receipts show an increase of £7,916. 13. 1d. compared with the corresponding period of last year, mainly due to the continuance of the insurrection followed by the Spanish-American war. £15,553. 8s. 10d. has been added to reserve, which, after deducting £7,550. 15s. 0d., balance of cost of the Manzanillo-Santiago cable, and £4,002. 13s. 10d. for cable repairs, now stands at £110,000. The dividend on the preference shares will absorb £3,000, and leave £10,113. 11s. 6d., out of which the Directors recommend the payment of a dividend at the rate of 6 per cent. per annum, and a bonus of 2s. per share on the ordinary shares, both free of tax, £3,713. 11s. 6d. being carried forward.

The cable between Manzanillo and Santiago was successfully completed in February last, and the broken Cienfuegos-Santiago section joined up at Cape Cruz, thus restoring communication between Cienfuegos and Santiago by the 1881 cable.

The Directors regret that owing to the operations of the war considerable damage was done to the Company's property, but the board are pleased to report that since the termination of hostilities the broken cables have been repaired, with the exception of the Cienfuegos-Casilda section, and the 1891 cable between Cienfuegos and Batabano, which will be put in order as soon as possible. Notwithstanding these interruptions, the Directors are glad to state that the through communication has been continuously maintained, the staff remaining at their posts under very trying circumstances.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 28d. per oz. (Nov. 17). Consols (2¾ per cent.) 110¼—110⅜ for money, 110⅜—110½ for account; 2½ per cent. 104¾—105¼ (Nov. 17), Stock Exchange Settling Days: Consols, Dec. 1; Stocks and Shares Continuation Days, Nov. 28 and Dec. 13; Ticket Days, Nov. 29 and Dec. 14; Pay Days, Nov. 30 and Dec. 15; Mining Share Carry-over Days, Nov. 26 and Dec. 12.

CHELSEA ELECTRICITY SUPPLY CO. (LIMITED).—Letters of allotment and regret for the recent issue of £40,000 Four and a-Half Per Cent. Debenture Stock have been posted.

EASTERN AND SOUTH AFRICAN TELEGRAPH CO. (LIMITED).—In another page will be found the numbers of 441 Five Per Cent. £100 Mortgage Debentures drawn for payment at par on Jan. 2 next at Messrs. Barclay and Co.'s, 54, Lombard-street, E.C.

EDISON AND SWAN UNITED ELECTRIC LIGHT CO. (LIMITED).—During the week the London Trust Co. offered for subscription at 99 £150,000 Four Per Cent. Debenture stock of this company.

R. HORNSBY AND SONS (LIMITED).—The directors recommend the payment of dividend on the Preference stock to Sept. 30, including arrears, at 6 per cent, and a dividend of 6s. per share on the Ordinary shares, free of tax, for the year ended Sept. 30, placing £5,000 to reserve. In 1895-96 only a dividend on account was paid, and the year closed with a debit balance of £10,784. So severely were the effects of the engineers' strike felt in 1896-97 that no dividend was paid on even the Six per Cent. Preference, but the debit balance was reduced to £8,189. The directors are, therefore, to be congratulated upon the success of their efforts during the past year.

POTTERIES ELECTRIC TRACTION CO. (LIMITED).—During the week subscriptions were invited on behalf of this company, which has a share capital of £400,000, for 20,000 Five per Cent. Cumulative Preference and 13,334 Ordinary shares of £10 each.

THE PROPOSED AMALGAMATION OF GERMAN ELECTRICAL FIRMS.—The provisional agreement for the amalgation of the undertakings of the Schuckert Co. and the Ludwig Loewe Co., particulars of which were given in our last issue, has been cancelled.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Nov. 11 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £3,124.

WEST INDIA AND PANAMA TELEGRAPH CO.—Subject to final audit the directors have decided to recommend a dividend of 6s. per share on the first and second Preference shares, and 1s. 6d. per share on the Ordinary shares for the six months ended June 30 last; the Ordinary share dividend free of tax.

WILLANS AND ROBINSON (LIMITED).—The registers of the Debenture stockholders and of transfers of this company are closed from 16th to 29th inst. inclusive.

NOTES.

PROF. FORBES had a mixed audience of engineers, students and laymen at the Society of Arts on Wednesday evening to hear his Paper on "Long Distance Transmission of Electric Power," and what probably aroused most interest among the listeners was his "simple financial transaction which copper merchants or others would willingly make, and which may avoid the huge capital hitherto required by those who transmit the power, and will increase the dividends on money spent on transmission"—in a case, given as example, increasing the net income from 9 to 40 per cent. The financial scheme comes simply to this: the capital is divided into two parts, the major part is represented by copper and is a 4 per cent. mortgage on the transmission line, while the smaller part spent on hydraulic and electric machinery will produce a net income equal to 40 per cent. of this part of the capital when the interest on the mortgage has been paid. Although Prof. FORBES may be only an amateur financier he must surely know that, with the same capital, revenue, and working expenses, the same total profit or loss will be made whether the capital is divided merely into ordinary shares or into ordinary shares and a mortgage. Consequently, taking the first-mentioned 9 per cent. investment as a basis, if the ordinary shares, with a possible return of 40 per cent. on a speculative undertaking, be a sounder investment than this, the mortgage bonds must have a lesser value; and if, on the other hand, the 4 per cent. mortgage on the security of some copper cable strung up in another continent be a better security, the ordinary shareholder will be the sufferer. Is not Prof. FORBES' "simple financial transaction" merely the one known as robbing Peter to pay Paul, with, perhaps, an element of uncertainty thrown in as to who is to be Peter and who Paul?

CHINA would seem to offer a good field for the development of electrical engineering enterprise. From an article by Messrs. J. S. FEARON and E. P. ALLEN, in the November number of the *Engineering Magazine*, we gather that the country is rich in coal, iron and other minerals, and that the natives possess a highly developed civilisation, and are industrious and peace-loving. To demonstrate what can be done with native labour, it is mentioned that an arsenal has been in operation near Shanghai for nearly 30 years under British superintendence, and that the 2,000 Chinese workmen who are employed there have developed a very satisfactory skill. The telegraph is stated to be the only institution of modern science which has obtained any considerable foothold in China proper:—

> Peking is connected by wires with Tientsin and with Manchurian points up to the Russian frontier, whence connection is continued by Russian Siberian lines to Europe. The capital is also connected with all the treaty ports and principal cities in China proper, and these again with each other. Canton has connection also through Yünnan with Burma. China learned the value of the telegraph in the war with France, and it has long since been admitted to have "become indispensable." The telegraph, however, s under Imperial control, and there is probably little opportunity for its extension as a private enterprise. Chinese writing being not alphabetic but syllabic, and there being as many characters as there are words in use, the telegraphic messages are sent in a number cypher. For transcribing messages received a double-ended type is used; on one end is the character, and on the other the corresponding number. When a message is received it is set up by the numbers, and then printed from the reverse or character, end.

SHOULD, however, any of our readers contemplate the starting of an enterprise in the Celestial Empire, it is as well to remind them that, in spite of his "highly-developed civilisation" and his "industrious and peace-loving" disposition, the Chinaman "has some force of character, and resents most strongly the encroachment of the 'barbarian,' as he terms all outlanders—resents it not merely as the savage African does, but with patriotic feeling and a natural desire to owe his progress to no one but himself." This being the case, we should advise electrical engineers to confine their operations, for the present at any rate, to those parts of the country which fall within the British sphere of influence.

Digitized by Google

THE interest in the recent breakdown at Brighton appears wide-spread, and various opinions are being expressed as to the means which should be employed to prevent the recurrence of such an accident, many central station engineers being of opinion that the minimum cut-out should be suppressed. In another column we publish an article by Mr. ARNOLD PHILIP, offering some further suggestions as to the possible cause of the mishap. The experiment described was, of course, merely on a laboratory scale, and hardly conclusive; for the arrangement of a hedgehog transformer and a battery does not represent precisely the same conditions as the field coils and armature of a shunt dynamo running on a load. Nor need we look to the armature reaction of the disabled machine only, but to that of all the machines, as a cause contributing to the reduction in the dynamo pressure; this has already been pointed out by us. Our contributor's article, however, helps to put some of the properties of paralleled shunt machines in a clear light, and his suggestion, that the short circuit of the 'bus-bars by the disabled armature might have brought the machines to the unstable condition represented by the lower limb of a shunt characteristic, merits more than passing consideration.

THE following letter, signed by the Chairman of the Electricity Committee and the resident engineer, has been sent to electric light consumers in Edinburgh :—

Sir or Madam,—We respectfully and earnestly appeal to you in the present unfortunate crisis in the electric lighting undertaking of Edinburgh, hitherto so successful. Relying on promises of plant delivery, which were not fulfilled, new consumers were connected up in large numbers during summer and autumn, and we are now unable to deliver current at the standard pressure during the hours of heaviest load, from 4 p.m. to 7 p.m. The consumers can help us in this difficulty by arranging to light only two-thirds of the lamps usually required during the above hours. If this is done more light will be got from the remaining lamps than if they were all on, as the full pressure can be maintained. If the switches do not suit, the necessary lamps can be unshipped. As soon as we can get the plant in sufficient order due intimation will be given. We trust to your complying with this request, assuring you that every effort is being made to put the plant in a more satisfactory condition, and with the least possible delay.

While sympathising with the supply authorities in their difficulty, we cannot but think that their position is somewhat undignified, and not altogether blameless; for, although the contractors are as usual chiefly in fault, the supply authority might have safeguarded itself by the exercise of a little ordinary business foresight. An assumption of "masterly inactivity" a few months ago, in the matter of making house connections, might have averted the present crisis.

IN another column will be found several items of interest with regard to the telephone situation. At Glasgow an unexpected difficulty has cropped up, the town clerk (Sir JAMES MARWICK) refusing to have anything to with the Glasgow Bill, in course of preparation, for powers to establish and work a municipal telephone exchange. Sir JAMES justly considers it illegal for the "Common Good" to be included as a guarantee for the scheme, and that the rates only could be used for that purpose; and as the Committee will not be influenced by his opinion, he has decided to take the course indicated above. In the meanwhile the National Telephone Co. have made a counter-move, offering the Glasgow Corporation a new scale of rates for all subscribers on the basis of a reduced minimum charge for a maximum of 500 conversations per annum, with a supplementary charge for each conversation above that number. This offer is made on condition that the Corporation grant those facilities and wayleaves so often asked for but refused. It will be instructive to see how the Glasgow municipality will view this alternative to embarking the ratepayers' money in and guaranteeing by the "Common Good" an undertaking which must be terminated in twelve years' time. We notified last week that Manchester had decided to abandon its intention of applying for a telephone licence.

THE proceedings in the London County Council on Tuesday were also noteworthy. A member who had evidently taken cognisance of Mr. GAINE'S letter to *The Times*, published in abstract in our last issue, and asked whether 900 persons in London were actually unable to get telephonic connection owing to the Council's refusal to allow the Company to lay underground wires. Mr. BENN'S statement to the effect that the prime cause was the Company's refusal to concede equitable terms should be compared with the statements in the letter alluded to.

THE accounts of the Shoreditch electricity works having been referred back to the Lighting Committee "to allocate the disposal of the profits," we will defer for the present our promised examination until the Committee's further report is presented.

King's College, London.—The Council have appointed Mr. Ernest Wilson, M.I.E.E., Professor of Electrical Engineering, in succession to the late Prof. John Hopkinson.

Royal Society.—Among the Papers down for reading yesterday was one by Mr. C. T. R. Wilson, "On the Condensation Nuclei produced in Gases by the Action of Röntgen Rays, Uranium Rays, Ultra-Violet Light and other Agents."

Cable Interruptions and Repairs.—

	Date of Interruption.	Date of Repair.
St. Louis and Noronha	Oct. 17, 1898 ...	—
Pernambuco–Ceara	Oct. 19, 1898 ...	Nov. 22, 1898
Ceara–Maranham	Nov. 15, 1898 ...	—

Personal.—The Berlin correspondent of the *Daily Chronicle* hears that Prof. Röntgen, of Würzburg, has received a flattering invitation from the University of Leipzig to fill the chair which is about to be vacated by Prof. Wiedemann. Prof. Röntgen has the matter under consideration.

The Röntgen Society.—The President of the Röntgen Society and Mrs. Charles Mansell Moullin gave a conversazione at St. Martin's Town Hall, Trafalgar-square, on Monday night. The company numbered nearly 1,400, and included a number of the leading lights of the medical profession, besides several eminent physicists.

Light Railways; Important Decision.—The Board of Trade have intimated to the British Electric Traction Co. that they cannot confirm the order of the Light Railway Commissioners to construct an electrically-driven light railway between Coatbridge and Airdrie "because of the effect the scheme would have on the Caledonian and North British Railway Co.'s undertakings."

Society of Arts.—Among the recipients of the Society's medals for Papers read during last Session are :—Capt. B. F. S. Baden-Powell, for his Paper on "Kites: their Theory and Practice;" Prof. J. A. Ewing, for his Paper on "Linde's Method of Producing Extreme Cold and Liquefying Air;" and Prof. Silvanus P. Thompson, for his Paper on "Telegraphy Across Space."

Students of the Institution of Electrical Engineers.—The students' annual general meeting was held on the 16th inst., when a vote of thanks was passed to Mr. S. S. Grant, the students' honorary secretary, and the following gentlemen were elected to serve on the students' committee for the ensuing session:—Messrs. M. R. Gardner, F. S. Muller, L. R. Morshead, R. Pope, W. G. Royal-Dawson and M. Solomon (Hon. Sec.).

African Telegraph Lines.—A Reuter's telegram states that the Berber-Suakin telegraph having been completed, telegraphic communication is now open between Cairo and Suakin and Kassala over the Egyptian and Suakin military lines. Information has also been received by the Church Missionary Society to the effect that the telegraph line from the coast to Uganda is now open to the public for a distance of over 300 miles into the interior.

Salomons Scholarship.—The Scholarship founded by Sir David Salomons in connection with the Institution of Electrical Engineers, and annually bestowed on the recommendation of a Committee of the Institution, has this year been awarded to Mr. H. J. Tomlinson, a student in the Pender Electrical Laboratory at University College, London. By the conditions of the Scholarship the holder is required to spend a third year in study or research, and the successful candidate will continue to work in the Pender Laboratory under Dr. Fleming.

The Hopkinson Memorial at Cambridge.—The Engineering Laboratory Syndicate, says *Nature*, have lost no time in proposing a plan for the Hopkinson Memorial Building. The new wing will adjoin the present laboratory, and provide a lecture room, three laboratory-rooms, and small rooms for students engaged in research. For the completion of the plan some £500 will be required, in addition to the £5,000 generously given by Mrs. Hopkinson and her children. It is expected that the building will be ready for occupation in October, 1899.

Lord Armstrong's Experiments on Electric Discharge.—Prof. Stroud, of the Durham College of Science, gave a lecture on the 9th inst. on "Lord Armstrong's Experiments on Electric Discharge," in the theatre of the Newcastle Literary and Philosophical Society. The lecture was illustrated by numerous experiments with a 16-plate Wimshurst machine, driven by a motor; this machine, together with other apparatus, having been presented by Lord Armstrong to the Durham College of Science for the purpose of continuing the experiments on electric discharge which he had initiated.

Death of Sir John Fowler, Bt.—The death of this eminent engineer, which occurred at Bournemouth on Sunday last, after a prolonged illness and in his 81st year, creates a blank in the higher ranks of the engineering profession not easily made good. His name has been prominently before the country in connection with almost all the triumphs of railway construction throughout the British empire during the present century. Although not an electrical engineer, Sir John Fowler was associated as consulting engineer with the City and South London Railway and with the Central London Railway now in process of construction.

Falcon Works Engineering Society.—Mr. Percy Sellon delivered the Presidential Address to the above Society at the Inaugural Meeting of the present session on the 17th inst., at Loughborough. After referring to current and prospective developments in the electrical industry, Mr. Sellon passed on to consider the position of the British manufacturer of electrical produce in the face of competition from the Continent and America, and contrasted the conditions as regards labour, materials, and supervision of the respective systems in present operation in Great Britain, Germany, Switzerland, and the United States. Mr. Sellon concluded by referring to the changes and extensions which have been, and are now being, introduced at the Falcon works, including the introduction of the single-break day, the growth of the piece-work system, the Company's profit-sharing scheme, &c.

A Large Highland Water Power Scheme.—Parliamentary notice has been given of a bill for the purpose of carrying out an extensive water power utilisation scheme in the North of Scotland. It is proposed to erect a generating station near Loch Leven and utilise water power derived from the neighbouring river and lochs, as far as Loch Ericht. Dams are to be constructed to divert the waters of the Allt Glas into Loch Ericht, and for the purpose of raising the waters of Loch Ericht by damming the River Ericht where it flows out of the south end of the lake so as to submerge the neighbouring land. An aqueduct will be built as a communication with the two streams, Allt Coire a' Guibhais and Allt Dubh Garbh, and the waters of these streams will also be impounded. In a similar manner, by a series of dams and aqueducts, use will be made of all the small lochs and streams between Loch Ericht and Loch Leven.

A Temperature-Entropy Chart.—We are informed that Messrs. Frost and Sons, of Rugby, have been entrusted by Captain Sankey with the publication of the temperature-entropy chart devised by him. The basis of this chart is the water line and saturated steam line described by Mr. J. Macfarlane Gray in his Paper on "The Rationalisation of Regnault's Experiments on Steam" (*Proc.* Inst. Mech. E., July, 1889), and the space between these lines is closely divided by "constant pressure" and "constant volume" lines, which are extended into the superheated steam field; lines of constant dryness fraction are also given. There are scales giving total heat, water heat and internal energy, from which these quantities can be read off without interpolation. This chart embodies in a graphic form all the physical properties of steam used in thermodynamics from 100°F. to 400°F., and by its help thermodynamic problems can be graphically solved and the $\theta\ \phi$ diagram of a steam engine cylinder readily plotted from the indicator diagram.

Deaths from Electric Shock.—An unusual number of deaths from electric shock have taken place lately in America, judging by a long list published recently in the *Western Electrician*:—An employé of the Cedar Rapids (Iowa) Electric Light and Power Co. was killed recently while replacing a burned-out transformer with a new one in one of the Company's circuits. Another workman was killed while repairing a defective arc lamp in Beloit, Mich. He had been working on the switchboard during the afternoon, and, it is thought, failed to connect up the circuits properly before turning on the current. An unusual accident happened recently in Salt Lake City. The accident was caused by a telegraph wire, in course of erection, coming into contact with six big feed wires of the Union Light and Power Co. One of the workmen, who had hold of the reel of wire, received a fatal shock. Two men were killed by live wires at Baltimore during a heavy rainstorm. In one instance, the current was transmitted by the steel rod of an umbrella coming into contact with an arc light, and in the other case, the victim was bidding a friend good-bye, and rested his hand against an awning-pole, which had by some means become charged.

The Resistance of the Human Body.—At the instance of the Verband Deutscher Elektrotechniker Messrs. Siemens and Halske have been conducting a series of measurements of the electrical resistance both of their own workmen and of the men employed at the sugar factory at Oschersleben, where the recent fatal accidents occurred from low-pressure shock (see *The Electrician*, Vol. XL., p. 346). The range of the apparatus was from a few hundred to 150,000 ohms. Measurements were first made between the two hands of workmen employed at the Oschersleben factory, to see if the skin resistance was diminished by the chemicals used at the works. As values from 900 to 2,000 ohms were obtained, it was concluded that this was not the case. Measurements were then made between the hand and earth, the men in each case wearing the wooden shoes customarily worn by German workmen. Twenty-five of the men employed at ordinary work had resistances of over 150,000 ohms; in seven cases the resistance lay between 50,000 and 150,000 ohms, and in two other cases the values were 17,000 and 14,000 respectively. At the sugar factory

Digitized by Google

much lower measurements were made. In the evaporating room the resistances were between 1,700 and 900 ohms, in the cooling house between 2,400 and 1,100, and in the boiler house 3,000 to 1,200. One man with new shoes in the repairing shop offered more than 150,000 ohms' resistance, and the remainder varied from 7,000 to 1,300. In the sugar separating room the limits were 50,000 and 3,000 ohms, and in the machine room six measurements of over 50,000 ohms were made, two over 20,000, and one over 10,000.

Electric Railway Signalling.—For some months past, according to the *Evening Standard*, a section of the Great Northern Railway, 25 miles in length, has been used for a series of experiments on an electrical system of railway signalling. It is the invention of Mr. Wynford Brierley, who has devoted considerable attention to devising a mechanical arrangement for ensuring communication between signalmen and engine drivers, even in the most foggy weather, when visual signalling becomes impossible. The driver receives the signal on his engine. A contact bar fixed to the rails in a rocking shaft is connected by a lever and wire with the ordinary signalling apparatus, so that when the danger signal is set in the box, the contact bar is raised in position to strike a lever fixed on the locomotive. This completes an electric circuit, and sets an alarum ringing on the engine, which works an indicator. An ingenious form of double volute spring holds the engine contact bar vertical, allowing it to preserve a horizontal position in either direction. After receiving the blow from the contact bar on the rail, it performs a few oscillations, and resumes its vertical position in readiness for the next contact. The contact bars, both on the engine and the rails, have two ends, one for danger and one for safety. The safety lever has its own independent electric circuit, and moves an indicator on the engine. The danger bell continues to ring until reset by a simple apparatus, which also acts as a bell tester. The safety bell rings for a couple of seconds, and shows the word "Safe" on the bell. The bell ceases to ring, in this case, as the lever ceases to oscillate, and the word "Safe" disappears. It will be seen that the driver receives a distinct signal as to whether the semaphore signals are or are not against him. In the former case, he would stop the train in the shortest possible time, and communication would be made to him by bell signal code from the signal box. Even in clear weather this apparatus would prevent the signal box being overrun, and the driver would not again move until a permissive signal had been received.

Subfluvial Conduits.—Drawn-in systems for underground cables have of late years found more favour in the United States than in this country, and have several advantages in the case of work executed in busy cities, but it is hard to see how the expense of such systems laid in the bed of rivers can justify their adoption in place of armoured cables laid directly in the water. Two conduits of this class have, however, recently been laid across rivers in Boston, and are described in the *Electrical World*, of New York, of Oct. 29. The one consists fundamentally of seven wrought-iron pipes 4in. in internal diameter and ¼in. thick, with tight screw couplings, each pipe being covered to prevent corrosion with alternate layers of Bermuda asphalt and cheesecloth to a depth of $\frac{3}{16}$ths of an inch. The seven pipes are maintained in a proper relative position by wooden diaphragms from 2ft. to 3ft. apart, 16in. in external diameter and about 4in. thick, with holes for the pipes and split into four pieces to allow assembling. The whole is enclosed in a wooden shell with a thickness of 4in. and an external diameter of 24in., the shell being a regular wooden water pipe sawed lengthwise into two sections, which are grooved and spiked together. These sections vary in length from 1½ft. on the curves to 6ft. on the straight runs. All the wood was carefully creosoted before use. The half sections are bound together and around the diaphragms by bands or hoops of ⅜in. by 2in. strap iron set up with bolts and nuts. The conduit is in the form of a large U or inverted siphon, with about 48ft. between risers and a length of about 126ft. over all. It was assembled on the draw pier, and with a heavy beam across the upper end of the U and many stays and ties, was lifted on to a lighter, as shown in one of the illustrations, and lowered into the stream. A trench about 5½ft. deep had previously been dredged in the clay and rock bottom, the rocks being removed by divers. Into this trench the U was sunk until the upper surface of the horizontal section was 4ft. below the level of the bottom of the channel and the trench was then filled flush. Lead-covered cables have been drawn into the ducts, and it is the intention to keep the interior dry. If moisture cannot be kept out, it will be filled with a heavy oil to prevent corrosion. The other conduit is a much larger one, and of a radically new type of construction. It belongs to the Boston Electric Light Co., which has now in course of erection a new generating station in South Boston, to take the place of its four older stations in other parts of the city. The transmitting system from the new station into the city consists of two double conduits, one of which crosses Fort Point Channel near the Congress-street bridge. Each of these double conduits carries 24 ducts in four layers of six ducts each, they being double in the sense that the 12 ducts on one side of a vertical plane through the centre of the conduit run through manholes entirely distinct from the 12 on the other side. The lead-covered cables will be drawn into ducts solely of wood, the six layers of ducts consisting of semi-circular grooves planed in the opposite sides of seven layers of timbers, each layer being 6in. thick. The timber is untreated green pine, except for the sections passing through the mud line at the two terminals of the conduit, which for a distance of 12ft.—6ft. each side of the mud line—are of oak. This is for the purpose of avoiding the attacks of insects, which, experience has shown, are only made at these points. The timbers are fastened together at frequent intervals by ⅞in. galvanised iron bolts with nuts and washers, and also with kiln-dried soft-pine dowel pins, the former being expected to have a limited life and the latter to be more permanent. The swelling of the latter on reaching the water will render them very tight. These bolts and pins are passed through horizontally and vertically at intervals, making, with the staggered joints of the timbers, a very substantial construction. The bolt holes are counter-bored on one side of the conduit, in order to give a smooth surface for the launching, which was done from sliding ways. The length of the 6in. timbers varies from 4ft. on the curves to 20ft. on the straight run. The sections were assembled in the yard complete, except for the dowel pins, and the ducts were tested by means of a 3¼in. plunger attached to a bamboo rod for the curved runs, any sticking being remedied by taking down the structure and gouging out the ducts. At the joints each duct is flared out slightly to prevent a shoulder occurring to catch the piping. After the ducts were thus carefully rendered of a uniform minimum cross-section, each of the six sections of the conduit was assembled, fitted with dowel pins and taken on rollers to the launching ways. The conduit weighs in air a ton for about every 8½ft., making for the whole length a weight of about 40 tons. The launching ways were heavily lubricated with axle grease, and the back end was tilted up with jacks until the section slid off into the water. Each section was fitted with a stepped joint, with steps each 2ft. in length for attaching it to the next. These were joined in the water, and the whole sunk with weights.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, November 25th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Papers to be read: (1) "On the Properties of Liquid Mixtures," by R. A. Lehfeldt; (2) "On certain Diffraction Fringes as applied to Micrometric Observations," by L. N. G. Filon.

MONDAY, November 28th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II.—"Acetylene," by Prof. Vivian B. Lewes.

TUESDAY, November 29th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The Effect of Subsidence due to Coal Workings upon Bridges and other Structures," by S. R. Kay.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Iron-Constantan Thermo Couples.—It appears that H. Rubens was not the first to use thermo couples of iron and constantan for measuring radiant heat. Such thermo couples were calibrated or used by Holborn and Wien, Fuchs, Kleiner, Troost and Van Aubel. The latter gives an account of all these researches, the earliest of which is that of Fuchs, who published a Paper at Graz in 1893 on the thermo-electric behaviour of some nickel-copper alloys. Fuchs used baths of boiling alcohol, water, xylol, aniline and nitrobenzol to obtain standard temperatures ranging from 70deg. to 200deg. Kleiner found that the temperature curve is very nearly a straight line. Holborn and Wien used this thermo couple for measuring low temperatures, including the fusing points of some organic liquids; Troost used it for finding the boiling point of liquid ozone, and Van Aubel himself for determining the thermal conductivities of various alloys.

[Van Aubel, *Archives Sc. Phys. Nat.*, Geneva, 103, 4.]

Determination of Dielectric Constants.—If C_1 and C_2 are capacities inserted in a primary and a secondary circuit respectively, and i_1 and i_2 the currents, J. A. Erskine proves that i_2 changes very rapidly with C_2 when C_1 has certain values. Hence, if a suitable current indicator is available, the mutual influence of two circuits may be used for comparing two capacities with great accuracy, and hence also for the determination of dielectric constants. Such an indicator the author found in a set of magnetised bits of steel wire only 1cm. long. The primary current consisted of the discharge of an influence machine. The secondary coil was not enclosed in the primary, but was placed a few centimetres away, with the axes coinciding. The unknown capacity was determined by measuring the distance between the plates of a Kohlrausch condenser, when that and the condenser of unknown capacity produced the same demagnetisation of the needle. The curve of demagnetisations for various positions of the condenser plates being known, it was easy to find the capacity corresponding to the demagnetisation observed with the condenser containing the liquid to be studied. In order to maintain the constancy of the discharge potential the primary condenser was always charged very rapidly, as recommended by Jaumann.

[Erskine, *Wied. Ann.*, No. 10, 1898.]

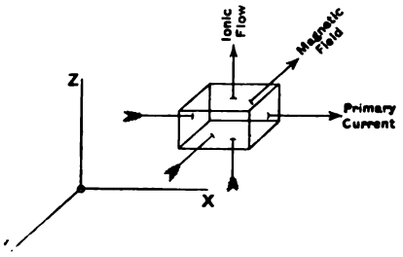
Crystallisation in a Magnetic Field.—The fact that any transparent, simply refracting, optically inactive substance, when placed in a powerful magnetic field, instantly acquires the property of rotating the plane of polarised light, and that the effect thereon is apparently of the same nature as that characteristic of certain specific atomic groupings in molecules, naturally raises the question whether, if the optically active molecular structure or aggregation were effected in a magnetic field, it would be influenced thereby to an extent sufficient to show an effect upon its final optical properties, which would seem probable, providing the interatomic or intramolecular forces are electro-dynamic. This question has been experimentally investigated by A. W. Wright and D. A. Kreider in the case of tartaric and racemic acids, sodium chlorate and ferrous sulphate. To determine the resultant optical activity of any crop of crystals, they were suspended in a mixture of alcohol and carbon bisulphide of the same refractive index, in a tube maintained in rotation by mechanical means. The results showed that even the strongest magnetic fields failed to control the direction of the resultant optical activity. But in the case of sodium chloride an excess of either dextro or lævo crystals was obtained, which indicated a kind of unstable equilibrium produced by the magnetic field.

[Wright and Kreider, *Am. Jour. Science*, November, 1898.]

The Constant of Gravitation.—The equation of gravitational attraction, $V = MM^1/d^2$, is not complete, as it requires the introduction of a constant depending upon the system of units adopted. That it is not complete may be proved in another way also. V is a force, and hence of the dimensions MLT^{-2}. The dimensions on the right-hand side are M^2L^{-2}. It is evident at once that the two sides are not dimensionally equivalent, and hence that other dimensions must intervene before the expression for the occurrence here represented is complete. If we put $V = KMM^1/d^2$, the dimensions of K necessary for a complete dimensional equation are $M^{-1}L^3T^{-2}$, a formula which is not yet interpreted. It depends, of course, upon the medium in which the gravitational action takes place. $M^{-1}L^3$ being the inverse of a density, the constant might be taken to signify the change in the rate of rarefaction of the medium in a given time. But before entering into speculations of this kind, it is better to determine the numerical value of the constant for C.G.S. units. F. Richarz and O. Krigar-Menzel have finished their long and laborious task at Spandau, and have found the constant to be $(6{\cdot}685 \pm 0{\cdot}011) + 10^{-8}$ $\frac{cm^3}{gr\ sec^2}$ by weighing a heavy mass at two different altitudes above the earth's surface. The corresponding density of the earth is 5·505, which accords fairly well with the value 5·527 found by Boys by means of his quartz-fibre torsion balance.

[Richarz and Krigar-Menzel, *Wied. Ann.*, No. 10, 1898.]

Hall Effect in Liquids.—F. G. Donnan calculates the much-controverted Hall effect in a binary electrolyte from the basis indicated in the diagram (*see* Fig.). The lines of flow of the primary current are supposed to be straight, and the magnetic field uniform. The effect of the ponderomotive forces on the moving ions in the magnetic field is to urge both positive and negative ions, with different velocities, in the positive direction of z. The stationary state is attained when the net flux of ionic matter in the positive direction of z is balanced by the flux of undissociated salt in the opposite direction. The author obtains transverse E.M.F.'s in a



$CuSO_4$ solution of the order of 10^{-7} volts, which would require a potential gradient of about 10,000 volts per centimetre to bring into measurable prominence. Hence, the conclusion is the same as that arrived at by Everdingen (see *The Electrician*, Vol. XLI., p. 488), viz., that Bagard's apparent Hall effect is due to other disturbing causes.

[Donnan, *Phil. Mag.*, November, 1898.]

Magnetic Deflection of Vacuum Discharges.—J. Henry has endeavoured to find the explanation of the change produced in the magnetic deflection of the discharge between a pair of electrodes in a rarefied gas, when the gas carrying the discharge is changed. The behaviour of such discharges closely resembles that of a flexible and elastic conducting string stretched between the electrodes. Such a string would be pulled aside while the magnetic force acted, and return to the straight line as soon as the magnetic force was removed. In order to avoid complications due to electrification of the sides of the tube, the author used a wide bell jar, closed by an ebonite plate, the electrodes being wires introduced through the neck of the jar and through the centre of the plate. The deflections were measured by photographing the discharges. The magnetic field was made vertical, and the deflection horizontal, thus avoiding distortions due to convection, at least on the photographic negative. It was found that, roughly speaking, the magnitude of the deflection increased with the density which the gas has at atmospheric pressure; in other words, with the molecular weight of the gas. As long as the current through the gas was kept constant, a change of pressure had little influence, if any. The potential difference between the electrodes was equally unimportant. The elements which determine the amount of magnetic deflection are exactly the same as those which determine the deflection by a blast across the electrodes, from whatever

Digitized by Google

cause produced. These elements are: The rate of diffusion of the gas, the rate of recombination of its ions, the velocity of the ions under a given E.M.F., the duration of the discharge, and the relative resistance of the gas to the passage of electricity through it before, and after, a discharge has passed. When the discharge is abrupt, the path is straight. When it is gradual, the chain of ions is blown aside by the blast due to the magnetic field.

[HENRY, *Phil. Mag.*, November, 1898.]

Phosphorescence.—H. Jackson attempts to connect together all the phenomena of phosphorescence, or what is more appropriately termed luminescence, with a view of showing between them a likeness in kind. The sources of luminescence thus dealt with include light, heat, chemical combination, cathode rays and X-rays. The glow of phosphorus, the fluorescence of quinine, the sparkling of heated chlorophane, the luminosity of Balmain's paint, the light from lime in a vacuum tube, the glowing of barium platino-cyanide under the influence of X-rays—all these phenomena may be looked upon as outward evidences of a response on the part of these substances to rapid oscillations. To avoid circumlocution the original response may be described as the assumption of a statical charge. The release of this condition of strain is accompanied by oscillations which give rise to the visible undulations of the phosphorescent light. So far the author's theory. It must be confessed that it does not give us much additional aid towards the solution of this complex problem. But a remark at the end of his Paper deserves attention. He supposes that the clouds in the solar photosphere are made up of matter in a more condensed or complex state than that of the solar nucleus or the photosphere itself. As a rule these clouds are rendered luminous by the more rapid oscillations of the nucleus. Occasionally, in the case of sun spots, they fail to shield the earth from these rapid oscillations, and electric disturbances result.

[JACKSON, *Phil. Mag.*, October, 1898.]

Arc Vapours.—In experiments upon the discharge of negative electricity by light, the electric arc has usually been found to be the most satisfactory source of ultra-violet rays. But it was early recognised that electrified particles, thrown off from the hot carbon terminals, and proceeding to considerable distances from the arc, might be a serious source of error. E. Merritt and O. M. Stewart have carefully examined the behaviour of the electrified particles thrown off by various arcs. They find that the vapours from the carbon arc possess the power of discharging electrified bodies with which they are brought into contact. In general the electric properties of these vapours are similar to those of gases that have been acted upon by X rays, or to the gases from a flame. This discharging power is retained even after the vapours have passed through long tubes of glass or metal, and lasts for at least 10 seconds. After passing between two grounded conductors, these being only a short distance apart, the vapours are found to discharge a negatively electrified body more rapidly than one charged positively. This recalls the action of X rays. The explanation of the phenomenon is probably that suggested by Zeleny, namely, that the negative ions diffuse more rapidly than the positive ones.

[MERRITT and STEWART, *Phys. Rev.*, Sept.-Oct., 1898.]

Electric Power Transmission in Canada.—In the United States consular reports from British Columbia it is announced that the work on the power plant and transmission line from Sooke Mountains to Victoria has been completed. The current is used for lighting and street railway purposes. The water from the mountains starts 2,300ft. above the level of the sea, and is the highest fall in Canada. About 750ft. above sea level and 16 miles from Victoria, these waters form a lake covering 150 acres, into which empties Goldstream river, which is tapped three miles from its source by an artificial lake or reservoir, covering 7½ acres, 1,122ft. above sea level. From this reservoir the water passes through a steel pipe 33in. in diameter, 6,700ft. to the power house of the electric company, which is 460ft. above sea level, thus giving a fall of 1,000ft. from the main lake, developing 1,500 H.P.

CURRENTS IN BRANCHED AND IN MUTUALLY INDUCING CIRCUITS PRODUCED BY HARMONICALLY VARYING ELECTROMOTIVE FORCES.

(*Concluded from page 74.*)

BY PROF. THOMAS R. LYLE.

Example II.

Two points between which a P.D. E subsists are joined in parallel by two conductors having R, L, and K, and exercising mutual induction on each other; determine the R and L of a conductor equivalent to the two parallels. Applying Kirchhoff's extended laws,

$$E + mC_2 = r_1C_1,$$
$$E + mC_1 = r_2C_2,$$

where

$$r_1 = R_1 + \iota\omega L_1,$$
$$r_2 = R_2 + \iota\omega L_2,$$
$$m = \omega M e^{-\iota\frac{\pi}{2}} = -\iota\omega M.$$

Hence, at once,

$$(r_1r_2 - m^2)(C_1 + C_2) = (r_1 + r_2 + 2m)E,$$

or

$$E = r^1(C_1 + C_2),$$
$$= (\rho + \iota\omega\lambda)(C_1 + C_2),$$

where ρ and λ are the resistance and inductance of the conductor equivalent to the two parallels, and may be shown to be given by

$$\rho = \frac{R_1R_2(R_1 + R_2) + \omega^2\{R_1(L_2 - M)^2 + R_2(L_1 - M)^2\}}{(R_1 + R_2)^2 + \omega^2(L_1 + _2 - 2M)^2}.$$

$$\lambda = \frac{R_1^2L_2 + R_2^2L_1 + 2MR_1R_2 + \omega^2(L_1L_2 - M_2)(L_1 + L_2 - 2M)}{(R_1 + R_2)^2 + \omega^2(L_1 + L_2 - 2M)^2}.$$

Two points between which a P.D. E subsists are joined in parallel by a number of conductors, each having R, L, and

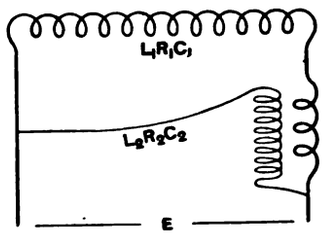


FIG. 5.

K. Determine the R and L of a conductor equivalent to the system and the phase difference of the currents in the several parallels.

If $C_n = c_n\cos(\omega t - \phi_n)$ be the current in parallel n, R_n its resistance and L_n its equivalent inductance, that is $\Sigma L - \frac{1}{\omega^2}\Sigma\frac{1}{K}$ in n, then putting r_n for $R_n + \iota\omega L_n$ we have,

$$E = r_1C_1 = r_2C_2 = r_3C_3, \text{ \&c.},$$
$$\therefore \Sigma C = \left(\Sigma\frac{1}{r}\right)E = \Sigma\left\{\frac{R}{I^2} - \iota\frac{\omega L}{I^2}\right\}E,$$
$$= (a - \iota\omega b)E,$$

where $a = \Sigma\frac{R}{I^2}$ and $b = \Sigma\frac{L}{I^2}$.

$$\therefore E = \frac{1}{a - \iota\omega b}\Sigma C = \frac{a + \iota\omega b}{a^2 + \omega^2b^2}\Sigma C = r^1C;$$

and as ΣC is the total current.

$$\frac{a}{a^2 + \omega^2b^2} = \text{resistance of equivalent conductor},$$

$$\frac{b}{a^2 + \omega^2b^2} = \text{inductance of equivalent conductor},$$

$$\text{also } \cos(\phi_p - \phi_q) = \frac{R_pR_q + \omega^2L_pL_q}{I_pI_q},$$

$$Sm(\phi_q - \phi_q) = \omega\frac{L_pR_q - L_qR_p}{I_pI_q},$$

where $\phi_p - \phi_q$ is the amount that C_q is *ahead of* C_p in phase.

Corollary I. To get the reduction factor of a Wattmeter.—Let the constants of the external circuit and thick wire coil of the wattmeter be R_1L_1, and those of the fine wire coil shunted across the terminals of the generator be R_2L_2. Fig. 5 making the arrangement clear.

The indication of the wattmeter is proportional to the average value of C_1C_2, that is, to $\frac{1}{2}c_1c_2\cos(\phi_1-\phi_2)$, or to $\frac{1}{2}\frac{c_1c_2}{R_2}\cos(\phi_1-\phi_2)$, as R_2 is constant.

The latter expression is

$$=\tfrac{1}{2}\frac{1}{R_2}\frac{e^2}{I_1I_2}\frac{R_1R_2+\omega^2L_1L_2}{I_1I_2}=\tfrac{1}{2}\frac{R_1R_2+\omega^2L_1L_2}{R_2I^2I_2^2}.$$

The power put into the external circuit is the average value of EC_1, that is,

$\frac{1}{2}\frac{R_1}{I_1^2}e^2$. Hence the reduction factor is $=\dfrac{I_2^2R_1}{R_1R_2+\omega^2L_1L_2}$.

Corollary 2.—If there be only two parallels the condition that the currents in them may be in quadrature (*i.e.*, $\phi_1-\phi_2=\frac{\pi}{2}$) is $R_1R_2+\omega^2L_1L_2=0$, which shows, since R_1 and R_2 are essentially positive, that L_1 and L_2 must be of opposite sign, that is, that in the one inductance must predominate, and in the other capacity. If $L_2=-\dfrac{1}{\omega^2K_2}$ where K_2 is the equivalent capacity of parallel 2, then the above condition becomes

$$K_2R_1R_2=L_1.$$

Example III.

If the alternate poles of the stator of a rotary field motor are wound with a continuous conductor, to determine the winding and constants of the conductor for the remaining poles, which conductor when joined in parallel with the first will split a single phase alternating current so as to produce a circular rotating magnetic field. Let $R_1L_1n_1$ (number of turns) I_1 reter to given circuit, $R_2L_2L'_2n_2I_2$, refer to required circuit, L_2 being the inductance of the stator coils, and L'_2 the added external inductance, which I have shown must be such as to make the total inductance $L_2+L'_2$ negative; in other words, capacity must predominate in circuit 2, and the capacity K_2 required to be put in will be $=-\dfrac{1}{\omega^2L'_2}$.

In addition, let p be the number of similar poles on one circuit of the stator, and σ the magnetic flux due to 10 ampere-turns round any pole. Hence for quadrature, that is, $\phi_1-\phi_2=\pi/2$,

$$R_1R_2+\omega^2L_1(L_2+L'_2)=0. \quad . \quad . \quad . \quad \text{(I.)}$$

For equal amplitude of magnetic flux

$$n_1c_1=n_2c_2,$$

that is,
$$\frac{I_1}{n_1}=\frac{I_2}{n_2}=a, \text{ say}, \quad . \quad . \quad . \quad . \quad . \quad \text{(II.)}$$

remembering that $I_2^2=R_2^2+\omega^2(L_2+L'_2)^2$;

also
$$\frac{L_1}{n_1^2}=\frac{L_2}{n_2^2}=p\sigma=\lambda, \text{ say}, \quad . \quad . \quad . \quad \text{(III.)}$$

and, as we have a condition still at our disposal, let it be that the volumes of copper on the two circuits shall be equal.

This gives
$$\frac{R_1}{n_1^2}=\frac{R_2}{n_2^2}=\rho, \text{ say}, \quad . \quad . \quad . \quad . \quad \text{(IV.)}$$

In the above, as λ and ρ are known and connected by the equation $a^2=n_1^2(\rho^2+\omega^2\lambda^2)$, we will also represent by τ the known ratio $\dfrac{\omega\lambda}{\rho}$.

By simple elimination we get at once $n_2=\tau n_1$.

Hence
$$R_2=\tau^2n_1^2\rho=\tau^2R_1,$$
$$L_2=\tau^2n_1^2\lambda=\tau^2L_1,$$
$$\frac{1}{\omega^2K_2}=-L'_2=n_1^2\rho\frac{\tau(1+\tau^2)}{\omega}=R_1\frac{\tau(1+\tau^2)}{\omega};$$

or
$$\omega K_2=\frac{1}{\tau(1+\tau^2)R_1}.$$

The energy drawn from the mains and received by the stator by circuit 1 is the average value of EC_1, while that by circuit 2 is the average value of $E'C_2$, where E' is the P.D. between the extremities of the stator coils of circuit 2.

Now $E^1=(R_2+\iota\omega L_2)C_2$,

$$\therefore \quad E=\{R_2+\iota\omega(L_2+L'_2)\}C_2;$$

hence
$$\frac{e^1}{e}=\sqrt{\frac{R_2^2+\omega^2L_2^2}{R_2^2+\omega^2(L_2+L_2^1)^2}}=\frac{n_2}{n_1}$$

after a few simple reductions.

Hence average EC_1 = average $E'C_2$, or the two circuits draw from the mains equal amounts of power. As τ for any motor circuit will always be a fairly large number (50 to 100) the above proves that we get in circuit 2 a P.D. across its stator extremities very much greater than the originating E.M.F. I will return to this subject in Examples V. and VI.

Example IV.—To Split a Single Phase Alternate Current into Three, which shall Produce a Circular Rotating Magnetic Field.

It is not possible to separate the phase of a current from that of the producing E.M.F. by more than $\pi/2$, but as we can wind a coil either right or left-handed, we can produce a magnetic flux differing in phase from the originating E.M.F. by any angle. If circuit 1 be given, *i.e.*, $R_1L_1n_1\phi_1I_1$, there are three cases.

a. When ϕ_1 or $\tan^{-1}\dfrac{\omega L_1}{R_1}$ is greater than 30deg. In this case we can arrange a parallel R_3, $L_2L'_2n_2$ 60deg. ahead of 1 in phase, and another parallel $R_3L_3L'_3n_3$ 60deg. ahead of 2 in phase, and wind circuit 2 on the stator in the direction contrary to 1 and 2.

b. When ϕ_1 is less than 30deg. and greater than −30deg. In this case we can arrange a parallel, $R_2L_2n_2$, 60deg. behind circuit 1 in phase, and another, $R_3L_3L'_3n_3$, 60deg. ahead of 1, and wind circuit 1 on the stator in the direction contrary to 2 and 3.

c. When ϕ_1 is less than −30deg. Treatment obvious.

Case *b* can obviously be easily reduced to case 1 by changing the numbers specifying the circuits.

Case A.—With the same notation and explanation as in Example III. we have (assuming no K in circuit 1) for equal magnetic flux

$$\frac{I_1}{n_1}=\frac{I_2}{n_2}=\frac{I_3}{n_3}=a, \text{ say}, \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(I.)}$$

$$\frac{L_1}{n_1^2}=\frac{L_2}{n_2^2}=\frac{L_3}{n_3^2}=\rho\sigma=\lambda, \text{ say}. \quad . \quad . \quad . \quad . \quad \text{(II.)}$$

$$\frac{R_1}{n_1^2}=\frac{R_2}{n_2^2}=\frac{R_3}{n_3^2}=\rho, \quad . \quad . \quad . \quad . \quad \text{(III.)}$$

i.e., equal volumes of copper in coils.

And as
$$\phi_2-\phi_1=\pi/3,$$
$$\phi_3-\phi_2=\pi/3,$$
$$\phi_3-\phi_1=2\pi/3,$$

we have
$$R_1R_2+\omega^2L_1(L_2+L'_2)=\tfrac{1}{2}I_1I_2,$$
$$R_2R_3+\omega^2(L_2+L'_2)(L_3+L'_3)=\tfrac{1}{2}I_2I_3,$$
$$R_1R_3+\omega^2L_1(L_3+L'_3)=-\tfrac{1}{2}I_2I_3.$$

After a little simple elimination we find,

$$n_2-\frac{n_1}{2}=\pm\frac{\sqrt{3}}{2}n_1\tau,$$

$$n_3+\frac{n_1}{2}=\pm\frac{\sqrt{3}}{2}n_1\tau.$$

τ, as in Example 3, being $=\dfrac{\omega\lambda}{\rho}$), and

$$\left(n_2-\frac{n_1}{2}\right)\left(n_3+\frac{n_2}{2}\right)=\tfrac{3}{4}n_1^2\tau^2.$$

Obviously in the second of last three equations the positive sign must be taken and the third then determines that the positive sign must also be taken in the first. Hence

$$2n_2=(\sqrt{3}\tau+1)n_1,$$
$$2n_3=(\sqrt{3}\tau-1)n_1,$$

which contain the solution of the problem.

Digitized by Google

Hence $$R_2 = \frac{(\sqrt{3}\tau + 1)^2}{4} R_1,$$

$$R_3 = \frac{(\sqrt{3}\tau - 1)^2}{4} R_1.$$

Similarly for L_2 and L_3.

Also $$\omega L'_2 = -\frac{(1+\tau^2)(3\tau + \sqrt{3})}{4} R_1,$$

$$\omega L'_3 = -\frac{(1+\tau^2)(3\tau - \sqrt{3})}{4} R_1.$$

In the same way, as in Example III., it can be shown that the powers drawn from the mains by the three circuits are equal.

Cases b and c.—In case *b* we can assume $R_2 L_2 L'_2 n_2$ given, and the above determines the constants of circuits 1 and 3; and in case *c* we can assume $R_3 L_3 L'_3 n_3$ given, and the above determines the constants of circuits 1 and 2. If the given circuit is without capacity, case *a* is the only one that would ever occur in practice.

Example V.

If a constant pressure alternating generator (E.M.F. = E) operate through leads with R and L into a condenser (cap. = K), it is possible to arrange the value of K so that the P.D. (= V) of the condenser plates may be greater than the originating E. In this case

$$E = rC \text{ where } r = R + \omega\left(L - \frac{1}{\omega^2 K}\right),$$

$$V = -\iota \frac{1}{\omega K} C.$$

Hence

$$\left(\frac{\text{amp. V}}{\text{amp. E}}\right)^2 \text{ or } \frac{v^2}{e^2} = \frac{\frac{1}{\omega^2 K^2}}{R^2 + \omega^2\left(L - \frac{1}{\omega^2 K}\right)^2} = \frac{1}{\omega^2 K^2 R^2 + (1 - \omega^2 LK)^2},$$

and it can be at once seen that $\frac{v}{e} > 1$ if ωK is less than $\frac{2\omega L}{R^2 + \omega^2 L^2}$, which $= \frac{2\tau}{R(1+\tau^2)}$, where $\tau = \frac{\omega L}{R}$.

Let $\omega K = \frac{2\tau}{R(1+\tau^2)} q$ where q is a positive number greater or less than unity, then $\frac{v^2}{e^2} = \frac{1+\tau^2}{1+(1-2q)^2\tau^2}$, from which we see that

$v < e$ when $q > 1$,

$v = e$ when $q = 1$,

$\frac{v}{e}$ a maximum $= \sqrt{1+\tau^2}$, when $q = \frac{1}{2}$, *i.e.*, when $\omega\kappa = \frac{\tau}{R(1+\tau^2)}$,

$v = e$ when $q = 0$.

The capacity of the condenser for maximum v is $= \frac{\tau}{R(1+\tau^2)}$.

Hence we see that if τ be a large number, and the capacity adjusted in accordance with the above, we can effect a multiplication of the P.D. in the ratio τqp. So by increasing τ and always adjusting K we can effect a multiplication of the P.D. to any extent we like. Now, τ being $= \frac{\omega L}{R}$, it may be increased by increasing ω or L or both. Hence if the rate of alternation $\omega/2\pi$ be alone increased and K correspondingly diminished, we can effect a high degree of multiplication.

For a fixed value of K there is a value of $\omega^2 = \frac{1}{KL} - \frac{R^2}{2L^2}$, which gives the maximum multiplication, and we can see that if K be very small, ω, and hence the multiplication ratio τ, may be exceedingly high. The following interesting problem is suggested by the above.

This problem must have an important bearing on most of the Tesla effects produced by currents of high frequency.

Example VI.

If two equal uniform leads are arranged between a constant pressure alternating generator and a condenser, as in Fig. 6, and if the resistance and inductance of these leads between the condenser and a point distant y from it be ρy and λy respectively, to find the value x of the amplitude of the P.D across the leads at the point y as a function of y. We have for the portion of the circuit between y and the condenser, including the condenser,

$$V - V_1 = \left\{ y\rho + \iota\omega\left(y\lambda - \frac{1}{\omega^2 K}\right) \right\} C,$$

and for the whole circuit

$$E = rC = \left\{ R + \iota\omega\left(L - \frac{1}{\omega^2 K}\right) \right\} C,$$

where $R = l\rho$, $L = l\lambda$, l being the length of the leads.

Hence we get the ratio of the squares of the amplitudes

$$\frac{x^2}{e^2} = \frac{y^2\rho^2 + \omega^2\left(y\lambda - \frac{1}{\omega^2 K}\right)^2}{I^2},$$

where I = impedance of whole circuit.

This immediately reduces to

$$\frac{x^2}{e^2} - \frac{\left(y - \frac{\lambda}{\omega^2 K}\right)}{\frac{I^2}{a^2}} = \frac{\rho^2}{\omega^2 K^2 a^2},$$

where $a^2 = \rho^2 + \omega^2\lambda^2$, the equation of a hyperbola. This can be represented in conjunction with the circuit, as in Fig. 5, by the curve ABD.

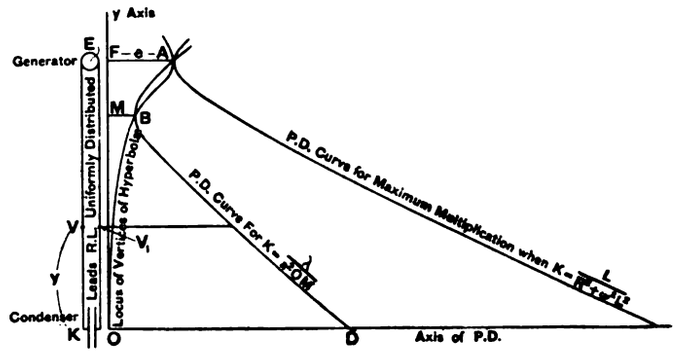

FIG. 6.

From the equation it is seen that the vertex of this hyperbola lies on the line $y = \frac{\lambda}{a^2 K}$, and it can be shown that the equation is satisfied by the point $x = e$, $y = l$ independently of the value of K. The P.D. at any point y is the abscissa between the corresponding point on the y axis and the curve, and it is seen that in the case which ABD represents that the P.D. at first falls on leaving the generator, reaches a minimum, and rises again. For each value of the capacity K there will be a corresponding hyperbola which will give the P.D. at all points along the leads. All these curves will pass through the point A, which represents the E.M.F. of the generator, and the vertices of them all will lie on a curve ABO, whose equation is

$$x^2\{(l-y)^2\tau^2 + y^2\} = e^2 y^2, \text{ where } \tau = \frac{\omega\lambda}{\rho},$$

the position of the vertex on this curve being given when K is given, as it has been shown, to lie on a line $y = \frac{\lambda}{a^2 K}$.

If the capacity, starting from a large value, be diminished, we see that at first when the vertices of the corresponding hyperbolæ lie between $y = o$ and $y = \frac{l}{2}$, which correspond to $K = \infty$ and $K = \frac{2\lambda}{a^2 l}$, that these curves cut off from the x axis a length less than FA, which means that when K lies between ∞ and $\frac{2\lambda}{a^2 l}$, or $\frac{2L}{R^2 + \omega^2 L^2}$, the P.D. at the condenser, is less than the E.M.F. of the generator; when B lies on $y = \frac{l}{2}$ OD becomes equal to FA, and for this $K = \frac{2L}{R^2 + \omega^2 L^2}$, as was shown

Digitized by Google

in Example 5. As K is still further diminished, OD becomes greater than FA, until the vertex falls on FA, when OD assumes its maximum value, the correspoding value of K being $\frac{L}{R^2+\omega^2L^2}$. Any further diminution of K diminishes OD, and when K = 0, OD finally becomes = FA.

Example VII.

Wheatstone's bridge, with R, L, and K, in all branches, using a telephone in place of a galvanometer, and a harmonic generator in place of the battery. Let X represent in amplitude and phase the current through the telephone, Y the current through arm 4, and Z the current through arm 3, then, referring to Fig. 6 and using Kirchhoff's extended laws, we get $r_2(X-Y)+r_1(X+Z)+r_5X=0$;

that is, $(r_1+r_2+r_5)X-r_2Y+r_1Z=0$,

where $r_1=R_1+\iota\omega L_1$, $r_2=R_2+\iota\omega L_2$, &c.

L_1, L_2 being the equivalent inductances of the arms,

$$L_1=L'_1-\frac{1}{\omega^2K_1}.$$

Similarly, $-r_2X+(r_2+r_4+r_6)Y+r_6Z=E$,

and $r_1X+r_6Y+(r_1+r_3+r_6)Z=E$,

which equations may be solved for XYZ, as if they were purely algebraical, giving

$$\Delta X=(r_2r_3-r_1r_4)E,$$
$$\Delta Y=\&c.;$$

but it must be remembered that the result is a vector equation, and that the functions Δ, $r_2r_3-r_1r_4$, &c., of the r's are operators.

X, the current through the telephone, is thus determined in terms of E and the constants of the bridge. For X = 0 the interpretation of $r_2r_3-r_1r_4=0$ is given below. In this simpler case, where it is only required to find the conditions between the constants for a balance to obtain, we may proceed *ab initio* as follows. (Refer to Fig. 6.)

$V_1-V_2=r_1C_1$, therefore

$$C_1=\frac{1}{r_1}(V_1-V_2)=\frac{1}{r_3}(V_2-V_4). \quad . \quad . \quad . \quad (I.)$$

for if no current goes through the telephone,

$C_1=C_3$, similarly,

$$C_2=\frac{1}{r_2}(V_1-V_3)=\frac{1}{r_4}(V_3-V_4). \quad . \quad . \quad . \quad (II.)$$

Now from I. we have $V_1-V_2=\frac{r_1}{r_3}(V_2-V_4)$,

$$V_1-V_3=\frac{r_2}{r_4}(V_3-V_4),$$

and as $V_2=V_3$ the operation $\frac{r_1}{r_3}$ must be identical with the operation $\frac{r_2}{r_4}$;

but $\frac{r_1}{r_3}$ may be represented by $\frac{I_1}{I_3}\epsilon^{\iota(\phi_1-\phi_3)}$,

and $\frac{r_2}{r_4}$ may be represented by $\frac{I_2}{I_4}\epsilon^{\iota(\phi_2-\phi_4)}$,

and for identity $\frac{I_1}{I_3}=\frac{I_2}{I_4}$, ... (III.)

and $\phi_1-\phi_3=\phi_2-\phi_4$, ... (IV.)

but when $\sin(\phi_1-\phi_3)=\sin(\phi_2-\phi_4)$,

$\phi_1-\phi_3=\phi_2-\phi_4$,

hence from Example II.,

$$\omega\frac{L_1R_3-L_3R_1}{I_1I_3}=\omega\frac{L_2R_4-L_4R_2}{I_2I_4}. \quad . \quad . \quad (IV.)$$

So, combining this with III., we get

$$\frac{L_1R_3-L_3R_1}{L_2R_4-L_4R_2}=\frac{I_1I_3}{I_2I_4}=\frac{I_1^2}{I_2^2}=\frac{I_3^2}{I_4^2}.$$

Hence $$\frac{L_1R_3-L_3R_1}{L_2R_4-L_4R_2}=\frac{R_1^2+\omega^2L_1^2}{R_2^2+\omega^2L^2}=\frac{R_3^2+\omega^2L_3^2}{R_4^2+\omega^2L_4^2}. \quad . \quad . \quad (V.)$$

are the necessary and sufficient conditions, for no sound in the telephone L_1, L_2, L_3 and L_4, representing the equivalent inductances, *i.e.*, L_1, stands for $L_1-\frac{1}{\omega^2K_1}$ where K_1 is any capacity that may be in arm 1.

The sign of the first term of (V.) is important, and as the other two terms are essentially positive for a balance it must always be positive.

Many interesting particular cases of the bridge with LRK, &c., might be discussed, but the author thinks he has given sufficient illustrative examples for the purpose of the present

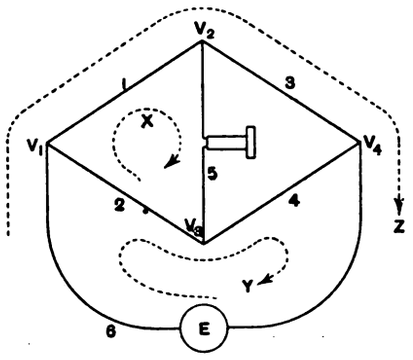

FIG. 7.

Paper; he hopes at some future time to return to the subject, and still further illustrate the convenience and power of the method brought forward.

THE LONG-SCHATTNER PREPAYMENT METER.

During the last two years there have been many workers at the problem of producing a cheap and reliable prepayment meter, but few of these inventors have up to the present succeeded in evolving instruments beyond the experimental stage. One of the main difficulties of the problem is that the meter must be capable of being manufactured and sold at a very low cost, and if frequent inspection or testing be needed this must be of the very simplest character; for it must be remembered that such apparatus are to be used by the smallest

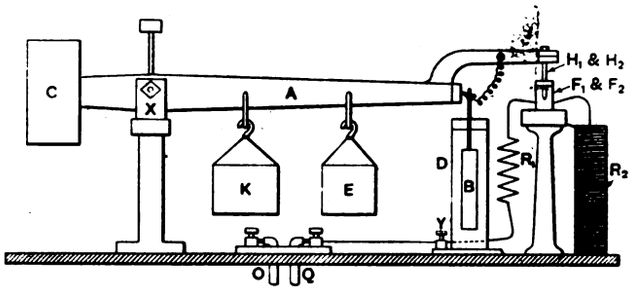

FIG. 1.—Diagram of Long-Schattner Prepayment Meter.

consumers, the revenue from whom would not justify the supply authority in making either a high capital expenditure or in spending any but a very small sum in maintenance. Another point, equally if not more important, which has to be observed by constructors of such meters is that an extremely low starting current is necessary; such meters must start at least when a single 8-c.p. lamp is switched on, *i.e.*, with a current of 0·15 ampere on a 200-volt supply network.

The electrolytic prepayment meter devised by Mr. F. M. Long, engineer and manager of the Norwich Electricity Co., in conjunction with his late assistant-engineer Mr. Schattner, and manufactured by Messrs. Schattner and Co., of Norwich, bids fair to fulfil these *desiderata*, and if its reliability is borne out by prolonged use it should prove a most serviceable instrument to the supply engineer. We understand that it is already used to some extent on the network at Norwich. Fig. 1 shows the principle diagrammatically. A is a lever

Digitized by Google

pivotted at X. At the far end of the lever is suspended a copper plate B, which is immersed in a solution of copper sulphate. The box D is also of copper, aud forms the cathode. C is a weight to balance the other side of the lever. K and E are cups to hold respectively the coins and standard weights which the collector replaces instead of the coins. F_1 and F_2 are mercury cups, F_1, the front one, being filled with mercury; F_2, the back one, being half filled with mercury and filled up with creosote oil. H_1 and H_2 are contact pieces forming a bridge across the mercury cups, aud fixed on the lever. R_1 is a main resistance, across which the voltameter is connected as a shunt, and R_2 is a large resistance permanently bridging the mercury cups. A diagram of the connections is shown in Fig. 2.

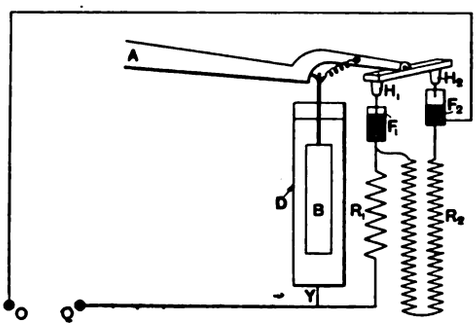

FIG. 2.—Diagram showing Connections.

Before the insertion of a coin the lever is in its higher position, and, the contact piece F_2 being out of the mercury, the current enters at the terminal O and passes through the resistance R_2 and out at Q to the lamps. When a coin is inserted the lever falls to its lower position, the resistance R_2 is short-circuited, and the lamps can burn at their normal brilliancy. It will be noticed that a low resistance R_1 is always in circuit, and it is to this that the copper voltameter is shunted. The anode being attached to the beam of the balance, as soon as a weight of copper has been removed equal to the weight of the coin dropped into the coin pan, the lever

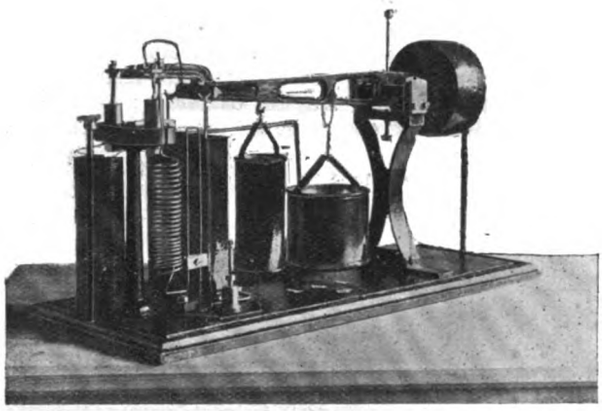

FIG. 3.—General View of Long-Schattner Prepayment Meter.

rises and the resistance R_2 is inserted, indicating to the consumer, by dimming the lamps, that he must either switch off or insert another coin. If the lamps are not switched off, and are left dim the company is not the loser as the voltameter remains shunted across the resistance R_1 and deposition of copper takes place, this being, so to speak, debited to the account of the next purchase of electrical energy. R_2 is calculated to produce a fall of pressure of about 70 volts when twenty 16 c.p. lamps are in use, but we think this is insufficient, for with a single 8 c.p. lamp the decrease of pressure by the insertion of this resistance would only be in the neighbourhood of two volts. True, if the decrease in brilliancy were not noticed, the extra energy consumed would be allowed for on the insertion of the next coin; and if attempts were made to cheat the meter in this way, the fact would be discovered by the inspector. Yet it would be best to avoid the possibility of such an occurrence.

The meter is designed for use with silver coins (3d., 6d. and 1s. pieces) whose weights vary approximately with their face values. Substitutes of baser metal would always be detected by the inspector, and there is no fear of loss by this means as in the case of an automatic meter in a public place, for of course the user of the instrument is responsible. The inspector who empties the coins from the meter is provided with a number of standard weights to replace them, and these compensate for any loss the consumer may have incurred by the use of worn coins, and at the same time afford a check on the inspector's takings. A new anode and cathode is needed every 700 units and these can be inserted without difficulty.

A uniform deposit of copper is ensured by leading the current to the top of the anode and away at the bottom of the cathode, and as a fairly low current density is employed, it is stated that there is no heating and no gassing even at higher loads. The creosote oil in the cup F_2 is said to be very effective in preventing sparking and preserving a clean contact at the break. A thin layer of ordinary machine oil is poured over the copper sulphate solution to hinder evaporation. Copper sulphate solution of 1·115 specific gravity is used, containing 1 per cent. of sulphuric acid. We are informed that the loss of pressure between the meter terminals is as follows:—

2 volts for 5 ampere meter, at 220 volts.

Fig. 3 is a general view of the instrument with the cover removed.

THE THEORY OF THE ROTARY TRANSFORMER.

BY GISBERT KAPP.

(COMMUNICATED BY LLEWELYN B. ATKINSON, A.M.I.C.E.)

(*Continued from page 116.*)

In the following investigations, Mr. Kapp assumes that the curves of E.M.F. and current are of sine form, stating that the effect of departure therefrom is not large. The case of single-phase converters both with and without phase displacement between E.M.F. and current is considered, and then the case of multiphase machines of 3, 4, and 6 phases.

Single-phase Rotary Transformer with Current in Phase.—In Fig. 3, the outer circle represents the winding, and d and f the

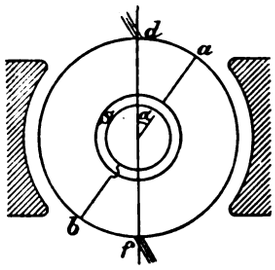

FIG. 3.

brushes for continuous current. The points a, b are connected to slip rings. The continuous current is taken as $2c$, so that each half of the armature has in it a current c. Assume that in the armature is an alternate current of effective value $2i$ and maximum value 2J. Let e be the E.M.F. of the continuous current, the effective value of the alternating E.M.F. will be $\frac{eK}{2}$, and the following equation shews the relation between the current input and output:

$$2i\,\frac{eK}{2} = 2ce,$$

given that

$$i = \frac{J}{\sqrt{2}}.$$

Then $\frac{2J}{\sqrt{2}}\,\frac{eK}{2} = 2ce$, whence $J = \frac{c2\sqrt{2}}{K}$, or $J = \eta c$.

The value of η depends on the ratio of the pole width to pole pitch, that is on the form and arrangement of the magnet fields, this ordinarily lying between $\frac{2}{3}$ and $\frac{1}{2}$. There is a

Digitized by Google

further case of some theoretical interest, which Steinmetz has considered, where the field strength is of strictly sinusoidal value, and for these cases η assumes the values

In the theoretical case $\eta = 2$.
With pole with $\frac{2}{3}$ of the pitch $\eta = 1{\cdot}9$.
" " $\frac{1}{2}$ " $\eta = 1{\cdot}72$.

If d is the positive and f the negative brush, then, in the position shown in the figure, current enters at a and leaves at b, and when the armature is rotating synchronously the current is $2J \cos \alpha$. This current divides, and the current in each armature winding is $J \cos \alpha = \eta c \cos \alpha$. There is also superposed the armature current c, so that, taking the four sections, we have as the resultant current

in fa $\quad c(1 - \eta \cos \alpha)$,
" ad $\quad c(1 + \eta \cos \alpha)$,
" fb $\quad c(1 + \eta \cos \alpha)$,
" bd $\quad c(1 - \eta \cos \alpha)$.

If w is the ohmic resistance of the winding on unit angle of the armature $\left(\text{that is, } \frac{180^\circ}{\pi} = 57^\circ\ 19'\ 80''\right)$ the resistance of the sections of the half armature are $w\alpha$ and $w(\pi - \alpha)$ and the power lost in each section is

in fa and bd $\quad 2wc^2(1 - \eta \cos \alpha)^2 (\pi - \alpha)$,
ad and fb $\quad 2wc^2(1 - \eta \cos \alpha)^2 \alpha$.

In the time dt the heat developed is

$$dA = 2wc^2\{(1 - \eta \cos \alpha)^2(\pi - \alpha) + (1 + \eta \cos \alpha)^2 \alpha\} dt.$$

Taking the angular velocity as ω, the frequency as $\curvearrowright$, and the periodic time as T,

$$T = \frac{1}{\curvearrowright}, \quad \omega = 2\pi \curvearrowright, \quad \alpha = \omega t,$$

$$dt = \frac{d\alpha}{\omega}, \quad dt = \frac{d\alpha}{2\pi \curvearrowright}.$$

The energy lost in a half revolution is

$$\int_0^{\frac{T}{2}} dA.$$

The mean value of the lost power is

$$P_v \int_0^{\frac{T}{2}} \frac{2}{T} dA = \frac{\omega}{\pi} \int_0^{\frac{T}{2}} dA.$$

Substituting the value of dA, above obtained, and transforming the integral for the angle swept out in time $\frac{T}{2}$, we have

$$P_v = \frac{2wc^2}{\pi} \int_0^{\pi} (\pi - 2\pi\eta \cos \alpha + \pi\eta^2 \cos^2 \alpha + 4\eta d \cos \alpha)\, d\alpha.$$

The solution of this integral gives the following values for the quantities under the integral

$$\pi^2, \quad 0, \quad \frac{\pi^2\eta^2}{2}, \quad -8\eta.$$

Using these values, and working out for the values of η, before given, we obtain

For the theoretical limiting case, $\eta = 2$. $P_v = \frac{2wc^2}{\pi}\, 13{\cdot}66$,

$m = \frac{2}{3}$, $\quad \eta = 1{\cdot}9$ $P_v = \frac{2wc^2}{\pi}\, 12{\cdot}56$,

$m = \frac{1}{2}$, $\quad \eta = 1{\cdot}72$ $P_v = \frac{2wc^2}{\pi}\, 10{\cdot}71$,

m being the ratio of pole width to pole pitch.

Now the power which would be lost in the armature copper by the current $2c$ if the armature were mechanically driven is $2\pi wc^2$, so that taking the ratio of this quantity to the values here tabulated we obtain in each case the ratio between the output as a converter and as a mechanical generator thus:

In the limiting case $\quad \frac{c}{c_1} = \sqrt{\frac{\pi^2}{13{\cdot}66}} = 0{\cdot}85.$

when $m = \frac{2}{3}$ $\quad \frac{c}{c_1} = \sqrt{\frac{\pi^2}{12{\cdot}56}} = 0{\cdot}88.$

$m = \frac{1}{2}$ $\quad \frac{c}{c_1} = \sqrt{\frac{\pi^2}{10{\cdot}71}} = 0{\cdot}95.$

As the outputs are in these ratios, the losses remaining the same, it follows that the efficiencies in each are only the above fractions of the efficiencies of the machine as a mechanical generator. The above figures relate to the case where the E.M.F. and current of the alternating side are in phase. The effect will next be considered of their being out of phase, but it may be noted that it is always possible to regulate the phase by regulating the exciting current.

Single-Phase Rotary Transformer with Phase Difference between E.M.F. and Current.—Fig. 4 shows the case where the excitation is such that the maximum value of the current is

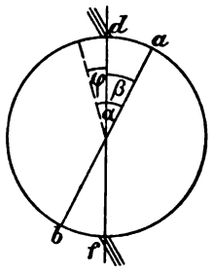

FIG. 4.

reached before the point of connection a has arrived at the brush d. If the angular displacement is ϕ, then $\alpha = \phi + \beta$.

The power in the alternate current is

$$\frac{2J}{\sqrt{2}}\, e\, \frac{K}{2} \cos \phi = 2ec.$$

$$J = c\, \frac{2\sqrt{2}}{K \cos \phi}$$

If we put $\quad \eta = \frac{2\sqrt{2}}{K \cos \phi}.$

$$J = \eta c$$

as before, only that η is now of greater importance.

It is unnecessary to repeat the process by which the following value of P_v is arrived at.

$$P_v = \frac{2wc^2}{\pi} \int_0^{\pi} \{(1 - \eta \cos \alpha)^2 (\pi - \beta)(1 + \eta\alpha \cos \alpha)^2 \beta\} d\alpha,$$

whence

$$P_v = \frac{2wc^2}{\pi} \int_0^{\pi} (\pi - 2\pi\eta \cos\alpha + \pi\eta^2 \cos^2\alpha + 4\eta\alpha \cos\alpha) d\alpha$$

$$- \frac{2wc^2}{\pi} \int_0^{\pi} 4\phi\eta \cos\alpha\, d\alpha.$$

The first integral is the same as with the current and E.M.F. in phase. The second is new. But, the value of the cosine integral between 0 and π being zero, this disappears, and this is independent of whether ϕ is positive or negative. In other words, it does not matter whether ϕ is positive or negative, except so far as it alters the value of η.

The solution of the first integral has before been given, and substituting the values we arrive at the following table:—

Output of Single-phase Transformers given in Percentages of the Output which the same Machine would give as a Continuous-Current Generator with the same Copper Heating.

cos ϕ.	1	0·9	0·8	0·7
Limiting theoretical case..	85	78	69	60
Pole width / Pole pitch $= \frac{2}{3}$	88	81	73	63
Pole width / Pole pitch $= \frac{1}{2}$	95	88	80	70

As will be noted, the machine of ordinary shape gives in every case a better effect than that in which the field strength follows a sine function. The case of multiphase rotary transformers now remains to be considered.

(*To be concluded.*)

ON THE INFLUENCE OF THE THICKNESS OF AIR-SPACE ON TOTAL REFLECTION OF ELECTRIC RADIATION.*

BY J. CHUNDER BOSE, M.A., D.SC.

In my preliminary experiments on the determination of the index of refraction of various substances for electric radiation, I used a single semi-cylinder of the given substance; the electric ray was refracted from the denser medium into air, and at the critical angle of incidence it underwent total reflection. The experiment was repeated with two semi-cylinders separated by a parallel air-space. With light waves an extremely thin air-film is effective in producing total reflection. But a question might arise whether waves a hundred thousand times as long would be totally reflected by films of air, and, if so, it would be interesting to find out the minimum thickness of air-space which would be effective in producing this result, This point was raised by Prof. Lodge, at the discussion on my Paper "On a Complete Apparatus for the Study of the Properties of Electric Waves," read before the Liverpool meeting of the British Association last year. I have for some time past been engaged in an investigation of this subject. The factors which are likely to determine the effective thickness of air-space for total reflection are :—(1) the index of refraction of the refracting substance; (2) the angle of incidence; (3) the wave-length of the incident electric radiation. In the following investigation, I have studied the influence of the angle of incidence and of the wave-length in modifying the thickness of the effective air-space. The refracting substance used was glass.

I. *Influence of the Angle of Incidence.*—The great experimental difficulty in these investigations lies in the fact that there is at present no receiver for electric radiation which is very sensitive, and at the same time strictly metrical in its indications. This difficulty is further complicated by the fact that the intensity of the electric radiation cannot be maintained absolutely constant. For these reasons it is extremely difficult to compare the results obtained from different sets of observations. Attempts have been made in the following experiments to remove, to a certain extent, some of these difficulties. Two semi-cylinders of glass, with a radius of 12·5cm., were placed on the spectrometer circle. The plane faces were separated by a parallel air-space. The radiator was placed at the principal focus of one of the semi-cylinders; the rays emerged into the air-space as a parallel beam, and were focussed by the second semi-cylinder on the receiver placed opposite the radiator. Electric radiation was produced by oscillatory discharge between two small circular plates 1·2cm. in diameter, and an interposed platinum ball 0·97cm. in diameter. The two semi-cylinders were separated by an air-space 2cm. in thickness; this thickness was found to be more than sufficient for total reflection. The critical angle for glass I found to be 29°. I commenced my experiments with an angle of incidence of 30° (slightly greater than the critical angle). The receiver, which was placed opposite the radiator, remained unaffected as long as the rays were totally reflected. But on gradually diminishing the thickness of air-space by bringing the second semi-cylinder nearer the first (always maintaining the plane surfaces of the semi-cylinders parallel), a critical thickness was reached when a small portion of the radiation began to be transmitted, the air-space just failing to produce total reflection. The *beginning* of transmission could easily be detected and the critical thickness of air determined with tolerable accuracy. The slight discrepancy in the different determinations was due to the unavoidable variation of the sensitiveness of the receiver. When the thickness of air was reduced to 14mm., the receiver began occasionally to be affected, though rather feebly. But when the thickness was reduced to 13mm. there was no uncertainty; a measurable, though small, portion of the radiation was now found to be always transmitted.

I now increased the angle of incidence to 45deg., and observed that the minimum thickness, which at 30deg. just allowed a small portion of radiation to be transmitted, was not sufficiently small to allow transmission at the increased angle of incidence. The thickness had to be reduced to something between 10·3mm. and 9·9mm. for the beginning of transmission.

With an angle of incidence of 60deg., the minimum thickness for total reflection was found to be between 7·6mm. and 7·2mm.

Angle of incidence.	Minimum thickness of air for total reflection.
30°	Between 14 and 13 mm.
45°	,, 10·3 and 9·9 mm.
60°	,, 7·6 and 7·2 mm.

The minimum effective thickness is thus seen to undergo a diminution with the increase of the angle of incidence.

* Paper read before the Royal Society.

II. *The influence of the wave-length.*—In the following experiments I kept the angle of incidence constant, and varied the wave-length. I used three different radiators, A, B, and C; of these A emitted the longest, and C the shortest waves. The following method of experimenting was adopted as offering some special advantages. If a cube of glass be interposed between the radiator and the receiver placed opposite to each other, the radiation striking one face perpendicularly would be transmitted across the opposite face without deviation and cause a response in the receiver. If the cube be now cut across a diagonal, two right-angled isosceles prisms will be obtained. If these two prisms were now separated slightly, keeping the two hypotheneuses parallel, the incident radiation would be divided into two portions, of which one portion is transmitted, while the other portion is reflected by the air film in a direction (*see* Fig. 1) at right angles to that of the incident ray, the angle of incidence at the air-space being always 45deg. The transmitted and the reflected portions would be complimentary to each other. When the receiver is placed opposite to the radiator, in the A position, the action on the receiver will be due to the transmitted portion; but when the receiver is placed at 90deg., or in the B position, the action on the receiver will be due to the reflected portion. The advantage of this method is that the two observations for transmission and reflection can be successively taken in a very short time, during which the sensitiveness of the receiver is not likely to undergo any great change. In practice three readings are taken in succession, the first and the third being taken, say, for transmission, and the second for reflection.

I shall now give a general account of the results of the experiments. When the prisms are separated by a thickness of air-space greater than the minimum thickness for total reflection, the rays are wholly reflected, there being no response of the receiver in position A, but strong action in position B. As the thickness is gradually decreased below the critical thickness, the rays begin to be transmitted. The transmitted portion goes on increasing with the diminution of the thickness of air-space, there being a corresponding diminution of the reflected component of the radiation. When the thickness of the air-space is reduced to about 0·3mm., no reflected portion can be detected even when the receiver is made

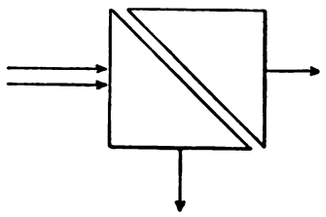

FIG. 1.—Section of the two Prisms.

extremely sensitive. The reflected component is thus practically reduced to zero, the radiation being now entirely transmitted; the two prisms, in spite of the breach due to the air-space, are electro-optically continuous. This is the case only when the two prisms are made of the same substance. If the second prism be made of sulphur, or of any other substance which has either a lower or a higher refractive index, there is always found a reflected portion even when the two prisms are in contact. Another interesting observation can be made by separating the prisms for total reflection. There would now be no transmitted portion. But if a thin piece of cardboard or any other refracting substance be now interposed in the air-space, a portion of the radiation will be found to be transmitted, and it will be found necessary to separate the prisms further to reduce the transmitted portion to zero.

Having given a general account of the experiments, I shall now describe the method of procedure. The radiator tube was provided with an ordinary lens whose focal distance for electric radiation is about 4 cm. The beam thus rendered approximately parallel fell perpendicularly on the face of the glass prism. The two prisms were made by cutting a cube of glass—an ordinary paper weight—across a diagonal. The size of the cube was 4·5cm. on each side.* One prism was fixed on the spectrometer circle; the other could be moved so as to vary the thickness of the interposed air-space between the two sections very gradually. The separation was simply effected by means of ordinary cards. The cards used were of uniform thickness, each card being 0·45mm. in thickness. A certain number of cards was taken and placed between the prisms with their surfaces in contact with the hypotheneuses. The cards were then carefully withdrawn, leaving the prisms separated by a thickness of air equal to the thickness of the given number of cards. It would, of course, be an improvement to have a micrometer screw by which the thickness may be gradually increased. Observations were now taken to determine the minimum thickness of air for

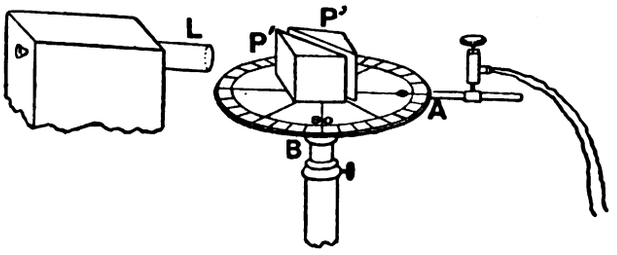
* Larger prisms would have been preferred had they been available. The prisms after cutting were found to be approximately isosceles, the angles being 90deg., 46deg., and 44deg.

Digitized by Google

total reflection for different wave-lengths, the angle of incidence being in all cases kept at 45deg. Three radiators, R_1, R_2, R_3, were used. I have not yet made determinations of the lengths of wave emitted by these radiators, but it will be seen from the dimensions of the radiators that the waves emitted by R_1 are the longest and those emitted by R_3 the shortest. The oscillatory discharge in R_1 took place between two circular plates 1·2cm. in diameter and an interposed ball of platinum 0·97cm. in diameter. The radiators were enclosed in a tube 3·8cm. in diameter. In the radiator R_2, the discharge took place between two beads of platinum and an interposed sphere the same as in R_1. The distance between the sparking surfaces was 1·01cm. In the radiator R_3 sparking took place between two beads and an interposed sphere 0·61cm. in diameter. The distance between the sparking surfaces was 0·76cm. One prism was fixed on the spectrometer circle, and the other was at first placed somewhat apart from it; the distance was now gradually reduced till the air-space just ceased to reflect totally, when a small portion of radiation began to be transmitted. The beginning of transmission was detected by the receiver, which was placed in the A position. The detection of the beginning of tramsmission is, as has been said before, somewhat dependent on the sensitiveness of the receiver.

Radiator.	Distance between sparking surfaces in mm.	Minimum thickness for total reflection.
R_1	...	Between 10·3 and 9·9 mm. ..... (*a*)
R_2	10·1	„ 7·6 and 7·2 mm. ..... (*b*)
R_3	7·6	„ 5·9 and 5·4 mm. ..... (*c*)

From the above results it is seen that the effective thickness of the totally reflecting air-space increases with the wave-length. If the wave-lengths are proportional to the distance between the sparking surfaces which give rise to the oscillatory discharge, the wave-lengths in (*b*) and (*c*) are in the ratio of 101 : 76. This is not very different from the ratio of the corresponding minimum thicknesses of the totally reflecting air-space.



L is the lens to render the incident beam parallel; P, P', are the right-angled isosceles prisms; A and B are the two positions of the receiver. The receiver-tube is not shown in the diagram.

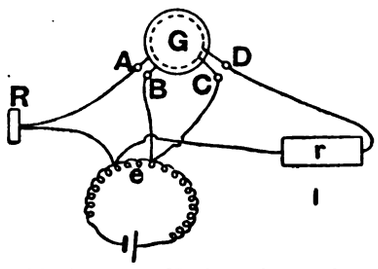
FIG. 2.

III. *On the Relation between the Reflected and the Transmitted Components of Radiation when the Thickness of Air-space undergoes Variation.*—In the general account of the experiments, I have said that as the thickness of air-space is gradually reduced the intensity of the transmitted portion of radiation is increased, while there is a corresponding diminution of the intensity of the reflected portion. This I have been able to verify qualitatively from numerous observations. But in making quantitative measurements many serious difficulties are encountered, owing to the difficulty of maintaining the intensity of radiation as well as the sensitiveness of the receiver absolutely constant.

As regards the first, the intensity of the emitted radiation depends on the efficiency of the secondary spark, and the nature of the sparking surface. Keeping the primary current that flows through the Ruhmkorff coil constant, the efficacy of the secondary spark is very much affected by the manner in which the contact is broken in the primary circuit. If a vibrating interrupter is used, the break is apt to become irregular; the torrent of the secondary sparks also spoils the sparking surface of the radiator. For merely qualitative experiments the use of a vibrating interrupter is not so very prejudicial, as along with the ineffective discharges there are present some which are oscillatory. But where successive discharges are to give rise to radiation of equal intensity, it becomes necessary to avoid all sources of uncertainty. For these reasons I prefer a single break for the production of a flash of radiation. With some practice it is possible to produce a number of breaks, each of which is effective. If the surface at the break is kept clean, and the break is properly effected, successive flashes of radiation up to a certain number are about equally intense. When the sparking has been taking place for too long a time, the surface no doubt undergoes a deterioration. But twenty or thirty successive sparks are equally efficacious when sparking takes place between platinum surfaces. The use of a single flash of radiation is preferable on another account. The receiver at each adjustment responds to the very first flash, but becomes less sensitive to the subsequent flashes. The conditions of the different experiments are maintained similar, when the action on the receiver is due to a single flash of radiation, instead of the accumulated effect of an unknown number of flashes. I give below the deflections of the galvanometer produced by four successive flashes of radiation.

(1) ..... 115 divisions.
(2) ..... 122 „
(3) ..... 113 „
(4) ..... 108 „

When very careful adjustments are made, the successive deflections are approximately equal. There are, however, occasional failures, owing either to the fault of the break, or loss of sensitiveness of the receiver. More serious is the difficulty in connection with the receiver. With the improvements adopted there is no difficulty, under any circumstances, to make the receiver very highly sensitive; but it is extremely difficult to maintain the sensitiveness absolutely uniform. I have in my previous papers explained how the sensitiveness of the receiver depended on the pressure to which the spirals were subjected, and on the E.M.F. acting on the circuit; and how the loss of sensitiveness due to fatigue was counteracted by slightly increasing the E.M.F. For each receiver there is a certain pressure, and a corresponding E.M.F., at which, for a given radiation, the receiver is sensitive. Having obtained these conditions, the sensitiveness can be increased or decreased to almost any extent by a slight variation of either the pressure or the E.M.F. An increase of pressure produced by the advance of the micrometer press screw through a fraction of a millimeter would sometimes double the sensitiveness; similarly an increase of E.M.F. of even $\frac{1}{100}$ volt increases the sensitiveness to a considerable extent. The nature of the difficulties in maintaining the sensitiveness of the receiver uniform will be understood from what has been said above. These difficulties are indeed great, and appear at first to be insuperable. But by very careful and tedious adjustments I was able on several occasions to obtain fairly satisfactory results, and was in hopes of ultimately obtaining metrical values from the galvanometer deflections. The setting of the rainy weather has unfortunately introduced other conditions unfavourable to the maintenance of uniformity of the sensitiveness of the receiver. Owing to the excessive damp and heat the spirals get rusty in a short time, and variation in the sensibility is produced by the altered condition of the surface of the sensitive layer. The results of certain experiments I have carried out lead me to hope that this difficulty will, to a certain extent, be removed by covering the sensitive surface with a less oxidisable coating.



G, the differential galvanometer; R, the receiver: *r*, the resistance box.

FIG. 3.

The deflections produced in the galvanometer can only be taken approximately proportional to the intensity of the absorbed radiation. It would be better to observe the diminution of the resistance produced by the incident radiation. This may be done with the help of a differential galvanometer and a balancing resistance. G is a high-resistance differential galvanometer, with two sets of electrodes, A, B; C, D; one pair of electrodes is in series with the receiver, and the other with a resistance box. When the receiver is adjusted to respond to the electric radiation, a weak current flows through it. The same E.M.F. acts on both the circuits. The compensating current, produced by a proper adjustment of the resistance of the box, brings the spot of light back to zero. The resistance of the box is equal or proportional to the resistance of the receiver. When radiation is absorbed by the receiver the resistance is decreased, and this diminution of the resistance is found from the new balancing resistance.

All observations agreed in showing that as the thickness of air-space was gradually decreased, the transmitted component was increased, with a corresponding decrease of the reflected portion. I give below two sets of observations, in which the receiver acted better than usual. The results are to be taken more as qualitative, as no reliance can be placed on the sensibility of the receiver being absolutely uniform.

Radiator R_1; distance between the sparking surfaces = 10·1mm.

Digitized by Google

Thickness of air-space in terms of number of cards.	Thickness in mm.	Galvanometer deflection due to the reflected portion.	Galvanometer deflection due to the transmitted portion.
1	0·45	0 or very slight.	Against the stop.
2	0·90	Slight.	" "
4	1·8	80	160
8	3·6	145	150
10	4·5	150	120
12	5·4	160	100
16	7·2	Against the stop.	30
18	8·1	" "	0

It is seen from the above that, as the thickness of the air-space was gradually increased, the reflected component increased, while the transmitted portion decreased. The minimum thickness for total reflection was found to be about 8mm. When the thickness of air-space was reduced to about half this thickness (slightly less than half) the reflected and the transmitted portions seemed to be about equal. With the radiator R_1 the minimum thickness for total reflection was found to be about equal to the thickness of 22 cards (9·9mm.). When the thickness of air-space was reduced to the thickness of 10 cards (4·5mm.) the reflected and the transmitted portions seemed to be about equal. As two experiments immediately following each other are more likely to be comparable, the experiments were so arranged that the observation of deflection for *transmission* with a certain thickness of air followed the observation for *reflection* with a different thickness, the corresponding deflections being about equal. As stated above, the reflected and the transmitted portions were approximately equal when the thickness of air was equal to the thickness of 10 cards. Keeping 10 as the mean, pairs of readings were taken with different thicknesses. For example, the reflection reading with a thickness of air equal to the thickness of four cards was followed by taking a reading for transmission, with a thickness of air equal to the thickness of 16 cards; the deflections produced in the two cases were about equal, *i.e.*, 66 divisions of the scale.

I append below a table showing the corresponding thicknesses of air (in terms of number of cards) which gave approximately equal deflections, the deflection in one case being due to the reflected component, and in the other case to the transmitted component. The receiver was made moderately sensitive, so that the deflections lay within the scale. When the thickness of air was reduced to 0·45mm. a deflection of two divisions was obtained for the reflection reading. From this an approximate idea of the intensity of the reflected component may be obtained. Half the total radiation gave a deflection of 120 divisions. The intensity of the reflected component, with a thickness of 0·45mm., is, therefore, $\frac{1}{120}$th part of the total amount of incident radiation, on the assumption, which is only approximate, that the galvanometer deflections were metrical. When the thickness was reduced to 0·3mm., no reflected component could be detected, though the receiver was made extremely sensitive.

Thickness of air for reflection.	Thickness of air for transmission.	Deflection produced.

ELECTRICITY WORKS ACCOUNTS.

Dewsbury Municipal Electricity Supply Works.

Our first table this week contains analyses of the Dewsbury accounts for the *fifteen months* ended March 31,1897, and for the *year* ended March 31, 1898, this latter period being the third completed year of working, electricity supply having started at Dewsbury on December 10, 1894.

Of the £25,000 of authorised capital, £24,881 has been received, borrowed at rates varying from 2½ per cent. to 3¼ per cent., £500 at 3 per cent., and £100 at 3¼ per cent. has been repaid. The expended capital at March 31st last amounted to £25,308, representing £92 per kilowatt of generating plant. During the last year under consideration the number of consumers has increased by 34, bringing the total up to 101. Corresponding with this the equivalent 8-c.p. lamp connection has increased from 6,817 to 8,056, or about 28 per cent.

The output for the year was 145,474 units sold, as compared with 150,878 for the preceding 15 months, showing a rise, estimated *pro rata*, of a little over 20 per cent. Consequent upon the introduction of the maximum demand system of charging for supply to public and private lamps, the average price obtained per unit has dropped from 5·94d to 4·65d.

A reduction of a little more than a farthing in the total cost per unit somewhat relieves the disappointing state of affairs betrayed by the slow increase in the business done, and the works costs at 1·65d. per unit are very satisfactory considering the low output. Management and property charges, as is to be expected, are high, but the figures representing these costs should, in all fairness, be discounted when we notice the electricity undertaking saddled with such items as "Town Hall Charges," £306; and "Diamond Jubilee Illuminations," £80.

A working profit of £935 has been made representing 3·78 per cent. of the mean capital. £682 has been allocated to the sinking fund, £732 paid as interest on loans and an adverse balance of £146 from the preceding period of working has resulted in a deficit of £625.

Bury Municipal Electric Supply Works.

Started on November 5, 1896, electric supply at Bury has completed but one year of existence. Our tables deal respectively with the accounts for the period from November 5, 1896, to March 31, 1897, and for the year ended March 31, 1898. The total authorised capital stands at £30,000. £28,595 has been borrowed, of which £50 has been repaid. The capital expended at March 31st last was £25,513, being at the rate of £84 per kilowatt of generating plant installed.

During the year the number of consumers has more than doubled, having increased from 41 to 84. The equivalent 8-c.p. lamp connection has risen from 2,481 to 6,155, or 150 per cent. The output for the year was 64,462 units sold, for which an average price of 4.91d. per unit was obtained.

Total costs at 2·9d., and works costs at 1·6d. per unit, are exceedingly satisfactory results at an output of only 64,000 units, especially during the first year of working, and we hope it will be found possible to maintain the satisfactory position and progress.

A working profit of £540 has been made, £548 paid in redemption of debt, and £570 as interest on loans, leaving a deficit of £579, which, like that of the preceding period, has been met by the rates.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician' is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 6d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 6d.	16s. 6d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. R. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 2d., post free, 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

BRITISH PATENT LAW.

Our patent law has one peculiarity which, in our opinion, gives it a great advantage over that of other countries, namely the Provisional Specification. In spite of the carping of some would-be reformers, inventors as a rule are clearly of the same opinion, since they seldom avail themselves of the privilege allowed them of filing a complete specification in the first instance. When the publication of an abandoned provisional was prohibited by the Act of 1888, the only objection to such specifications which carried weight, as compared with their countervailing advantages, was, we think, done away with. A man may now file a provisional specification in a hurry to secure priority, and if he afterwards finds he has made a mistake can abandon it, without having it afterwards brought up in judgment against him to invalidate a patent granted on his later application. An historical sketch of the origin and development of the Patent Specification, including the birth of the provisional specification under the Act of 1852, is given in a book by Mr. Robert Frost, a notice of which will be found in another column. The practice in the Patent Office as regards grants of patents, oppositions thereto and amendments of specifications is very amply dealt with in this treatise. The author expresses regret that no official searches are made before a patent is granted, and thinks it would be a real benefit to inventors and the public if the Comptroller had power to refuse a patent on the ground of lack of novelty and invention, and that much expense would be saved to persons wrongly supposing themselves to be true inventors. Here our views do not accord with those of Mr. Frost. The suggested right of patentees to be saved expense by such means does not, we must confess, greatly impress us. In the first place it seems to ignore the ground on which a patent is granted, namely, that there is a bargain between the inventor and the State quite independent of the fees paid, which are merely a matter of office administration. The inventor alleges that he has valuable information to communicate, in consideration whereof the State grants him a patent, subject to a proviso that it shall cease if the information, which the

Digitized by Google

patentee has vouched for as valuable, proves to be valueless. Before the 1883 Act, when considerable sums were paid in advance, there may have been some hardship; but now that the fees are comparatively small and paid annually, it seems that the patentee gets strictly what he bargains for, namely, annual protection for an annual fee, with the right of renewal for 14 years, so long as the original consideration upon which the grant was made does not prove to have been illusory. Moreover, it seems unreasonable to suggest that the State should be required to maintain an army of skilled searchers sufficient to deal efficiently and expeditiously with thousands of applications on every conceivable subject, in order to tell every would-be patentee upon payment of a fee of £1, what he could learn upon payment to a patent agent of a fee more commensurate with the trouble his inquiry entails. If he is to have the right to get this information from the State, the initial fee on applying for a patent must be considerably increased, whereby the inestimable boon now enjoyed by inventors of getting provisional protection very cheaply would be taken away. But whether or not this is the right view to take, we emphatically dissent from Mr. FROST'S view that inventors would benefit by a change in the law such as he advocates. It is clearly only justice to an inventor that he should have the merits of his invention tried by the most competent tribunal. There are many cases where the question of anticipation is of such a difficult character, that it can only be justly decided after hearing the ablest scientific evidence, involving a trial which is quite unsuited to the Patent Office. If there were a right of appeal, which the author admits to be necessary, the inventor at the very inception of his undertaking, and before he has had time to prove the value of his invention, would find himself embarked in a costly patent litigation, which he might otherwise have avoided for several years, if not altogether, and in the meantime he would probably have found his invention either not worth fighting for, or else of an established value such as would enable him to provide for the cost of its defence. The alternative system of the refusal of a patent upon the *ipse dixit* of the Comptroller, acting on the report of an examiner, would undoubtedly result in many meritorious inventions being nipped in the bud, while the grant of a patent under such a system would merely imply a somewhat lesser probability than under the present practice that the patent would be afterwards upset.

A matter of historical interest, referred to in Mr. FROST'S book, is the rule of construction which has been adopted by the Courts at different times. So hateful had the monopolies granted in the reigns of Elizabeth and James I. become, that the statute passed in the twenty-first year of the last-named sovereign's reign, and which still remains the foundation of our patent law, was at first construed by judges with an eye directed chiefly towards its restrictive aspect; consequently, the tendency of the courts was to try and find out how the patentee could be defeated. Some generations passed before the recollection of the old oppressive patents of monopoly died out, when at length it came to be recognised that the statute was an enabling law, and that the patentee might be a person to be encouraged. The pendulum then for some time swung in an opposite direction, judges adopting what has been called a benevolent construction and trying to help the patentee as much as possible to maintain his patent. These oscillations have now settled down, and the judicial machine, like other good philosophical instruments, has become more dead beat. At the present time specifications are construed by our courts like other documents, simply by what they may with fairness both to the patentee and the public be taken to mean.

REVIEWS.

Law and Practice Relating to Letters Patent for Inventions. By ROBERT FROST, B.Sc. (Lond.). Second Edition. (Stevens and Haynes.)

The first thing which must strike anyone who takes up a modern treatise on patent law is its great bulk, and he will naturally inquire whether the subject might not have been dealt with equally efficiently in fewer pages. Mr. Frost tells us in his preface that his end has been to produce a work which in a reasonable compass shall reliably state the law of England in reference to letters patent. The second edition has been largely rewritten and added to, but by condensing the type in various ways the author has obviated the necessity, which might otherwise have been imperative, of putting his treatise into two volumes. When one comes to analyse the reasons for this prolixity it is found to be due in a great measure to repetition, and that of a kind which is common in legal text-books, perhaps in those of patent law more than any others, though we think that in certain matters Mr. Frost has carried it rather further than usual. For instance, in the chapter on specifications, which is, on the whole, a very good one, he treats of claims in a separate section, and there repeats a great deal which has been said before in dealing with the specification generally, sometimes in the very same words. The index of cases cited gives many which appear in more than 20 different places; though it is fair to the author to say that one case quoted 24 times in his book appears 32 times in another standard work.

Like other authors, Mr. Frost considers, under three headings, the elements required to maintain a patent, forming separate chapters on subject matter, novelty, and utility respectively. It may be convenient for the technical pleadings of a lawsuit, although we doubt whether even this is necessary, to keep these three things separate as grounds of objection to the validity of a patent; but by doing so in a treatise it is almost impossible to avoid overlapping, particularly as regards the first and second heads. In order to get a good patent it is not sufficient that the thing claimed should be merely new and useful, new, that is to say, in the sense of doing what has not been done before. You cannot claim the application of a known contrivance to a new purpose, unless there is some ingenuity in the application. There must be invention, useful invention, to provide subject matter for a patent; and saying this you cover the whole field dealt with in these chapters. The judicial decisions on subject matter mostly include the question of novelty also, and by treating both together not only would much space be saved, but we believe a clearer view of the subject would be obtained.

As to the amount of invention which is sufficient to support a patent, the law has laid down no very certain line. In the famous braided wire bustle case the patentee was held to be just inside the line, while in a more recent case a useful application of celluloid as a coating for boot eyelets was marked as just outside. Both these cases were decided by the House of Lords, where their lordships, as well as the judges below, showed considerable differences of opinion. It is interesting to notice that, of the cases quoted by the author on this part of the subject, no less than 33 were decided adversely to the patentee, while in only eight was the patent sustained. He has here, perhaps, unconsciously suggested a kind of empirical formula for the guidance of persons who hope to maintain patents for inventions of trifling merit, whereby they may learn that the odds against their succeeding is rather more than 4 to 1, probably a pretty near approximation to the truth.

A chapter is devoted to Specifications, and contains some interesting historical notes, and the all important questions as to the Patent Office procedure in granting of patents, in the event of amendments or oppositions, are treated fully. In so complete a treatise we need not look for much omission, but we are rather surprised to find no comment upon what is, perhaps, to the general public the most remarkable event since the passing of the Act of 1883. We refer to the order of the Board of Trade made during the current year directing the grant of the first compulsory licence. This weapon, which had

Digitized by Google

for 15 years remained almost forgotten in the armoury of the State, may now be considered as placed on the efficient list for service as a defence against a patent that is used oppressively.

The inventor who, on taking up the work before us, has been appalled by the magnitude of the subject, will no doubt lay it down with a chastened conviction that he and his class have no monopoly of the inventive faculty, while, if not of a most sanguine disposition, he may despair of ever effecting his escape from the manifold pitfalls which the cruel ingenuity of the lawyers has laid for him.

Wireless Telegraphy. By RICHARD KERR, F.G.S., with a Preface by W. H. PREECE, C.B., F.R.S. (London: Seely and Co. 1898.)

This little book of some 100 small pages attempts to explain in popular language the ideas which underlie the various systems of wireless telegraphy, and to describe the apparatus employed for its practical application. An inadequate amount of space is taken up by a biographical appreciation of Lindsay; it should be remembered that—as Mr. Preece also points out in his preface—this indefatigable worker was not the first wireless telegraphist. The discussion of the relative claims of Lodge and Marconi to priority of invention might without harm have been omitted, or merely dismissed with the statement that, although the possibility of telegraphing by means of Hertzian waves had clearly been indicated theoretically and experimentally by Lodge and others, the first successful experiments over long distances were carried out by Marconi. Cutting down the letterpress in these respects would have left space for a more complete description of the actual apparatus used, and a slightly fuller elucidation of the theory upon which its design is based. As it is, not even the general principles are enunciated in such a way as to enable them to be grasped by the lay mind. The best that we can say for the production is that for a shilling it will possibly enable the large section of the public, which has not had the benefit of scientific training, to learn as much—or as little—about the new methods of telegraphy as it knows of those methods in which line wires are employed. Good portraits of Mr. Preece, Dr. Lodge and Signor Marconi are among the illustrations.

Die Entwickelung der asymptotischen Telegraphie, der sogenannten elektrischen "Telegraphie ohne Draht," in allgemein verständlicher Darstellung sachlich und historisch erläutert. By Dr. RUDOLF BLOCHMANN. (Berlin: E. S. Mittler and Son. 1898.)

In spite of the length of the title, this is merely a 30-page pamphlet containing an expanded reprint of an article which appeared in the May number of the *Marine Rundschau*. It is a general description in simple language of the methods of telegraphing without line wires, and will probably be intelligible to anyone who has been through a good school course of electricity, and possesses, in addition, a knowledge of the German language. No great historical or technical accuracy is attained. When we say simple language we must except, however, the two monstrosities "Asymptotische Telegraphie" and "Hydrotelegraphie." If German pedantry cannot permit the use of the term "wireless telegraphy," on the ground that wires are essential at the transmitting and receiving stations, let it employ some such an expression as "Telegraphie ohne *fortlaufende* Drähte." The author does not make it quite clear why he considers this form of telegraphy asymptotic. "Asymptotische Telegraphie" he divides into three varieties—Hydro-, Induktions- and Strahlentelegraphie. The two latter titles are self-explanatory. Hydrotelegraphie is applied to that form of conduction telegraphy in which earth-plates take the place of the line-wire, although Dr. Blochmann is not oblivious to the fact that his method can be used for telegraphing across land as well as across water,

Les Ondes Electro-Magnetiques et la Telegraphie sans Fils. By A. DELLA RICCIA. (Liège: Imprimerie de la Meuse. 1898.)

Although also a reprint, this book is of quite a different character to the preceding. Lieut. Della Riccia's contribution to the subject of Hertzian telegraphy was first presented as a Paper to the Association des Ingénieurs Électriciens sortis de l'Institut Électrotechnique Montefiore, and has now been reprinted from the *Bulletin* of that Society. The author confines himself to the consideration of wave telegraphy by Signor Marconi's methods, and the book is rendered the more interesting by the fact that the author, who is a lieutenant in the Italian engineers, has been in continuous correspondence with Signor Marconi during the latter's experiments, and gives particulars of them which in many cases have not been published hitherto.

After a description of the apparatus used by Marconi, an explanation is given of the mechanism of the propagation of the electromagnetic waves in the ether. The treatment of this part of the subject is not beyond criticism, but it is the second part of the book, "Critical Examination of the Apparatus," that calls more particularly for our attention. This part begins with the modest disclaimer:—

Je déclare que plusieurs des idées que j'exposerai, à défaut des recherches expérimentales directes et de recherches analytiques avisées, n'ont pas un fondement bien certain; la pratique en sanctionerra peut-être quelques-unes et en rejettera d'autres. Mais mon intention est tout simplement d'attirer sur certains sujets l'attention de personnes plus compétentes que moi, afin que la nouvelle application puisse bientôt bénéficier de leur enseignement.

But even if Lieut. Della Riccia himself has not made many experiments, he appears to have thoroughly acquainted himself with all the details of those carried out by Marconi, and his theoretical explanations of the various phenomena observed under different combinations of these details, together with the deductions he draws from his investigations, make most interesting reading. The pieces of apparatus are considered one by one. In connection with the primary generator we note that, in his experiments at Dover (unfortunately written "Dower" throughout the book, in spite of the French name for the town being Douvres), Marconi tried severally a Tesla and a Thomson oil coil in place of the usual induction coil, but he found that the latter always gave the better results. A most ingenious hypothesis is advanced to explain why vertical wires in connection with the transmitting and receiving apparatus give better results than horizontal wires. The view put forward is that in the latter case, when the ray from the radiator is polarised in the plane of incidence, a deleterious interference takes place with the ray reflected from the surface of the sea. For a similar reason the author considers it advantageous to place the radiator itself (and also the resonator) with its knobs in a vertical line. With this arrangement, however, the bubbles from the oil between the knobs have a disturbing influence; this latter effect is less marked if smaller knobs be used.

Marconi wrote from Dover:—

It was determined that there is no advantage in employing a Righi radiator, as one can obtain the same effects by using two simple knobs (of about 2cm.) separated by a layer of air, as dielectric, having determined experimentally the most advantageous explosive distance. It is also interesting to know that, when sufficiently long vertical conductors are employed, it is unnecessary to rub or clean the surface of the knobs at the place where the sparks are formed.

During his experiments in the Isle of Wight, Marconi employed five knobs of 5cm. diameter, platinised where the sparks occur, and also without oil. Lieut. Della Riccia is of opinion, however, that the substitution of air for vaseline oil, as a dielectric, is a retrograde step. Marconi appears also to have made some rough quantitative experiments to arrive at a law connecting the length of the wire with the distance over which signals can be transmitted.

In the experiments made at Salisbury . . . it was ascertained that the distance, to which it is possible to correspond, increases more rapidly than in simple proportion to the length of the two vertical wires. However, it could not be determined whether the useful distance increases with the square of the length of the vertical conductors. Using kites designed by Capt. Baden Powell, and a rubber-covered copper wire of 2mm. diameter and 70 metres long for the double purpose of aërial conductor and kite-string, it was always possible . . . to correspond to a distance of 16 kilometres across country covered with little hills. Another test with a longer vertical wire (nearly 200 metres) gave satisfactory results to a distance of 54 kilometres (Salisbury to Bath).

At Dover the law of squares was verified in the case of wires 10 and 30 metres high. In the experiments between Alum Bay and Bournemouth the vertical conductors were 40 and 80 metres long respectively. Moving vessels with 16 metres of vertical wire attached to the masts were communicated with to a distance of 20 kilometres, even where there were natural obstacles such as elevated islands between the apparatus. Messages were also successfully transmitted 8 kilometres

Digitized by Google

through a hill whose base was 4 kilometres wide and whose height exceeded that of the longest mast by about 40 metres. In all these experiments induction coils were used capable of giving a 20cm. spark. The following notes are also interesting:—

In other experiments, also made at Salisbury, it was found advantageous . . . to employ, instead of one vertical wire, several parallel vertical wires about 30 metres apart each connected at the lower end to the same pole of the radiator. The same increase in the signalling distance can be obtained by using a wide network or metallic sheet in place of the parallel conductors. At the receiving station, an opposite effect, so to speak, was observed; that is to say, a greater distance when using a thin vertical wire, and no advantage in employing multiple wires or metallic sheets. At Dover it was found that on attaching large plates or capacities to the upper ends of the vertical, or nearly vertical, wires, the length of wire necessary for a given distance could be considerably reduced, in some cases, by using cylinders 1 metre long and 50cm. diameter. The length could be reduced to a third of what was necessary without capacity. . . .

In the Alum Bay trials:—

. . . It was found that when the length of the two wires is different, the effects can be greatly improved and brought to nearly the same value as when the two lengths are equal, by introducing in the shorter wire a coil or solenoid of thick well-insulated wire, with a certain capacity and self-induction. The number of turns of wire of this coil is determined by trial.

The author, while doubting strongly the reality of the curvature attributed to the electromagnetic rays in Mr. Preece's famous Royal Institution lecture, does not agree with the view that the rays actually traverse obstacles such as hills, &c.; he suggests instead a sort of diffraction effect. He is also sceptical about Marconi's statement that the distance over which communication can be maintained is greater in rainy weather. The only useful effect of the rain, according to Lieut. Della Riccia, might be to increase the capacity of the aërial conductors by wetting the insulation. The rain falling between the two stations would, he believes, cause a loss of electromagnetic energy, in the form of currents, induced in the drops.

Within the limits of this review we have, of course, only been able to touch on some of the various points raised by Lieut. Della Riccia. Those of our readers interested in the subject of Hertzian telegraphy should read his paper in its entirety.

RUNNING SHUNT DYNAMOS IN PARALLEL.

BY ARNOLD PHILIP, B.SC.

The recent breakdown at Brighton may give interest to the following considerations and the experiments upon which they are based. As is well known, special precautions are taken when shunt machines of different design are run in parallel. The speeds and the resistances in the shunts are adjusted so that, as nearly as possible, the electromotive forces of all the machines may fall and rise in the same ratio when the load on the bars varies. Thus, if the load increases, the consequent drop in the electromotive force developed in all the armatures must be the same. This drop in the electromotive forces is due to the increase of the back ampere-turns on the armature, the increase of the leakage coefficient and the decrease of the shunt current, and in order that the machines may share the new load in the same proportion as the old it is necessary that drop in the electromotive forces in all machines shall be the same. This means that either the machines shall be of identical design, or that if of different type the resistances in their shunts and their speeds shall be so adjusted that they shall all work at about the same magnetic induction in their field magnets. Such adjustment if carefully made may render it possible to vary the total load on the 'bus bars through a very large range without much disturbing the distribution of the total load among the machines, but in most cases some alteration of distribution is observable as the load varies, and if the adjustment has not been made very well a very large increase of load may cause the distribution of load to vary so greatly that a motoring of one or more of the machines might occur, that is, the load might be entirely removed from them and converted into a negative one. The greater the alteration of the 'bus bar voltage the greater is the danger that this accident may occur. If the machines whose loads are thus lightened are furnished with minimum current cut-outs they will not motor, but will be removed from the bars. The sudden drop in voltage on the 'bus bars may occur—

1. By decreasing the resistance between the 'bus bars, as, for instance, by a short-circuit of the bars.

2. Possibly by the breaking of a shunt circuit even when the armature had been removed from the bars.

3. By a short-circuit in the armature windings of one of the machines.

4. By suddenly switching out one of the dynamos when giving some considerable fraction of the total current,

In the case of a dead short-circuit of the 'bus bars, if all the machines are theoretically adjusted, they will first run up to the maximum currents they can give, and if they do not then burn out the short or their own armatures they will run round the lower limb of the shunt dynamo characteristic curve and cease to give any current at all, or if provided with minimum current cut-outs these will take them off the bars. If, however, one or more of the machines are working with their field-magnets excited to a flatter portion of the B H curve than the others, then when the short occurs their electromotive forces will not drop so much as is the case with the others, and they will, therefore, take most of the load, and the remaining machines, whose loads have thus decreased, will be cut out by their minimum current cut-outs; whilst, finally, the machines thus left on the bars will cut out with their excess current fuses, or if these are too large to blow with the maximum currents the machines can give, they will run round the lower limb of the characteristic curve and give zero current. The fact that at Brighton the main fuses on two of the machines are said to have remained intact whilst the machines were still on the bars appears to render the supposition that the breakdown was due to a dead short across the bars somewhat improbable.

As to whether the breaking of a circuit from 'bus bar to 'bus bar which has large self-induction and carrying a large current (such as the shunt coil of a machine) would cause any marked fall of pressure I am unable to say experimentally, as I have never had the opportunity of making the test upon a sufficiently large scale, and unless the coil so broken was very well insulated there would, of course, be a good deal of danger that its winding would be damaged. Possibly by using a transformer coil having very high inductance and carrying a considerable current, a test on this point could be made without any chance of damage, and would be of interest.

The third contingency, namely, the sudden short-circuit of the armature windings of one of the machines in parallel, will certainly cause a sudden fall in pressure across the mains owing to the large short-circuit current. An armature may have a short-circuit occur in its windings in so many ways that it is necessary for the sake of definiteness to select some particular one. Let us suppose that it is short-circuited by some accident from brush to brush, outside the brushes but inside the minimum cut-outs. The current in the armature would then suddenly increase enormously, and as the brushes have lead there would be a sudden weakening of the magnetic strength of the shunt field and consequently a sudden rise of E.M.F. across it in the same direction as would be the case if it were broken. In fact the armature would act like the primary of a step-up transformer of which the shunt windings form the secondary. The electromotive force thus set up in the shunt would act so as to lower the potential across the mains, or even possibly reverse it. It should also increase the armature currents of the machines still remaining in parallel, and weaken their shunt circuits.

In order to test the magnitude of the effect in this case, a shunt dynamo having an electromotive force of about 50 volts was coupled to the coil of a hedgehog transformer containing 2,960 turns, and having a resistance of 14·5 ohms. Ampere-meters, A_s and A_a, were placed respectively in the shunt and armature circuits of the dynamo, and a voltmeter V was connected across the shunt terminals. To the other coil of the transformer, which had a resistance of 0·1 ohms, and consisted of 192 turns; a small secondary battery was connected whose circuit could be closed or broken by means of a make-and-break key; an ampere-meter was also placed in

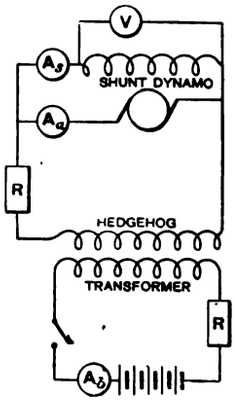
Digitized by Google

this circuit, and in both the dynamo and the battery circuit an adjustable resistance R was placed. The transformer was connected to the dynamo and the secondary battery in such a way that the field due to the current from the one was opposed to that due to the current from the other. It was then found on suddenly closing the battery circuit that :—

1. The volts on the voltmeter V fell ;
2. The current in the shunt circuit decreased ; and
3. The current through the armature increased.

These effects were reversed on opening the battery key. There is, therefore, no doubt but that the kind of action predicted takes place, but its magnitude in the experiment made was not greater than a fall of current in the shunt of about 2 per cent. of its original value. When it is remembered, however, that this experiment was made with a small hedgehog transformer about 2ft. long, and the current from the battery was only about 12 amperes at the maximum, it will, I think, be evident that very much greater effects are to be expected in the case of the short-circuited armature of a 220 kilowatt dynamo.

Lastly, the sudden removing of the armature from circuit by means of the minimum current cut-out would of itself cause a drop in the bars, and the two effects added together may account for the large similar type dynamos (if they were working on a less saturated field then the two smaller ones) cutting out and finally leaving the other two alone on the bars.



If the accident at Brighton was not due to a short on the 'bus bars, but is accounted for at all by the above facts, the fluctuation in a dynamo's field appears to follow the alteration of the exciting current more rapidly than one would expect. If the engines are governed for constant speed within small limits, such governing would, of course, assist in causing the minimum cut-outs to act, for it would prevent the weakened machines from increasing their speed as their loads diminished.

The instruments available for the above tests no doubt lagged a good deal in their indications, as their needles were heavy, and the damping was not inconsiderable, and it is possible that the alterations of current may have been really a good deal greater than was observed.

It may be added that even if all the dynamos in parallel have precisely similar armature reactions and are all working on the same portion of the magnetisation curve, yet a *sudden* fall of pressure on the bars may cause those machines whose shunt windings have the smaller time constants to drop their electromotive forces more rapidly than those machines whose shunts have larger time constants, and if this was the case at Brighton, one would expect that the shunt coils of two smaller machines had larger time constants than the larger machines whose minimum current cut-outs acted.

The Berlin Electricity Works.—After prolonged negotiations the Municipal Council of Berlin has signified its approval of a contract with the Berlin Electricity Works, permitting these firms to supply electricity to the city of Berlin until the year 1915, while the municipality is to participate in the profits to a certain extent.

ROTATORY CONVERTERS.*

BY PROF. SILVANUS P. THOMPSON.

(Continued from page 128.)

The relations between speed and field are peculiar. In the case of those grouped machines, or motor-dynamos (Fig. 3) in which each armature revolves in its own field, the conditions differ from those of the converter (Fig. 4), where there is only one field. If in either case the continuous-current side is the primary (*i.e.*, motor) side, the speed of revolution will depend on the field-magnet, the weakening of which will increase the speed. The frequency of the secondary or alternating current will in that case also vary. But the ratio of the primary and secondary voltages will be independent of speed if the fields are alike, or if only one common field is used. The secondary voltage cannot be varied, while the primary voltage is kept constant, unless separate field, and separate windings are employed, as in Fig. 3. If, on the other hand, the alternating current side is used as primary, then the machine, whether motor-dynamo or converter, runs as a synchronous motor with a fixed speed. In that case the voltage ratio remains also nearly a constant, even though the excitation of the field is increased or diminished, owing to the peculiar phase relations which take place, as is known, in the currents of synchronous motors when under-excited or over-

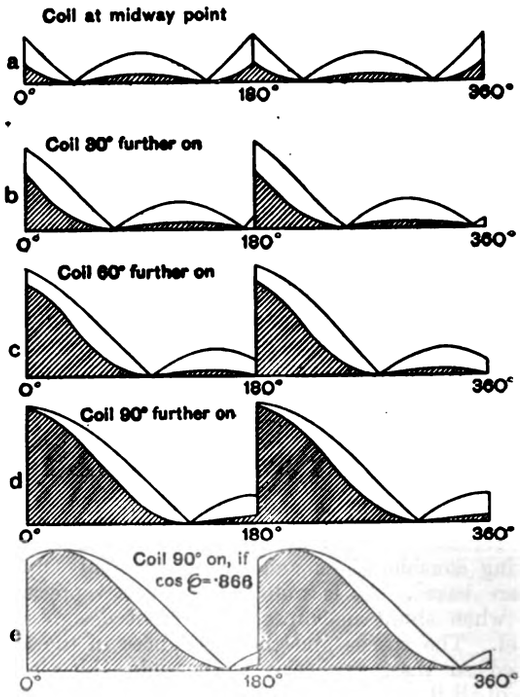


FIG. 6.

excited. This question, and the expediency of exciting in series or in shunt from the continuous-current side, or of running without excitation, has been discussed by Mr. E. J. Berg, in the *American Electrician* of February, 1897.

Returning to the question how the current in the armature of the converter gets through the windings, it will be found that a simple means of answering it is afforded by the principle of the superposition of instantaneous values of the currents. Still taking as a concrete case the 10-kilowatt converter of Fig. 3, we may calculate out the instantaneous values of the currents in its windings at different epochs in its period of rotation. If we do this for the motor currents and for the generator currents separately, and then superpose them, we shall obtain a number of instantaneous values for the combined armature as converter. This has been done in the series of drawings in Fig. 5. If the continuous current acts as motor taking 100 amperes, there will be 50 amperes flowing in each half of the winding at every instant—*qua motor*—in a direction opposing the electromotive force in the winding. This is shown in the first diagram in the upper row of Fig. 5. As single-phase generator the armature is working, as already described, with a virtual voltage of 70·7 volts, and an output (supposing the power-factor = 1) of 141·4 virtual amperes. The maximum current will be $141{\cdot}4 \times \sqrt{2} = 200$ amperes ; and this will be attained at the instant when the two conductors which lead down from the wind-

* Paper read before the Institution of Electrical Engineers, November 10, 1898.

Digitized by Google

ing to the slip-rings are turned to the position of 90deg. to the axis joining the middles of the pole-faces. The eight diagrams which follow in the top row of Fig. 5 exhibit the successive values of the currents flowing in the armature—*qua generator*—in positions differing successively by 15deg. By supposing these eight diagrams successively superposed upon the motor diagram which precedes them, we obtain the eight diagrams of the lower row, which exhibit the currents actually flowing in the different parts at the particular times when the armature has the position shown. Exmination of these diagrams shows several interesting points. At the instant when the alternating current is reversing, and each in position 0deg. being 50 amperes. But as the armature turns these change. They increase in the two arcs that are shortening as the points where the slip-ring connectors approach toward the positions occupied by the commutating brushes. But in the two other arcs that are lengthening, the currents first decrease to zero, then increase again to 50. Further, the individual coils in different parts of the ring winding have very different currents to carry. A coil that is midway along the winding between the two connectors has to carry never more than 50 amperes. Four times in each revolution it carries 50, and four times it carries 0 amperes, with values intermediate in intermediate positions. (This will obviously

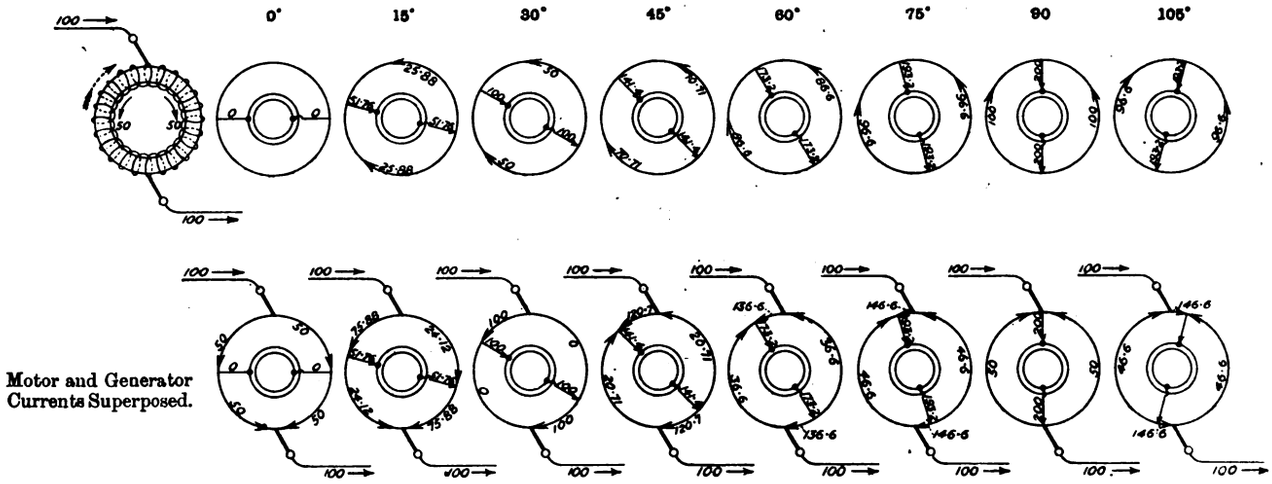

FIG. 5.—Flow of Currents in Single-Phase Converter. Continuous Current, 100 amperes at 100 volts. Single-Phase Current, 141·4 virtual amperes at 70·7 virtual volts.

has zero value (at position 0deg.), the armature is operating simply as a motor with 50 amperes in each half of the winding, and is being accelerated, At the 90deg. position, when the alternating current is at its maximum (200 amperes), the armature is operating wholly as a generator, and with an equal current of 50 amperes in each half of the winding, and the acceleration is negative. The armature is thus adding 100 amperes to the 100 amperes coming in from the primary mains. Nothing has here been allowed for the extra power needed to make up for the frictional and other losses. Suppose that an additional 4 amperes were needed for this, making set up four armature reactions in each period.) But a coil that is situated next to either of the two connectors has to carry a current which, when it is close to the brush position, rises to a maximum of 150 amperes, and changes abruptly to 50 in passing the brush; rising thus gradually twice to 150, or else rising twice abruptly from 50 to 150, and being zero twice, in one revolution. The necessary consequence of this is that the coils which are close to the slip-ring connectors are much more heated than those which lie midway along the periphery between the connectors. The distribution of the heating is here quite different* from that which

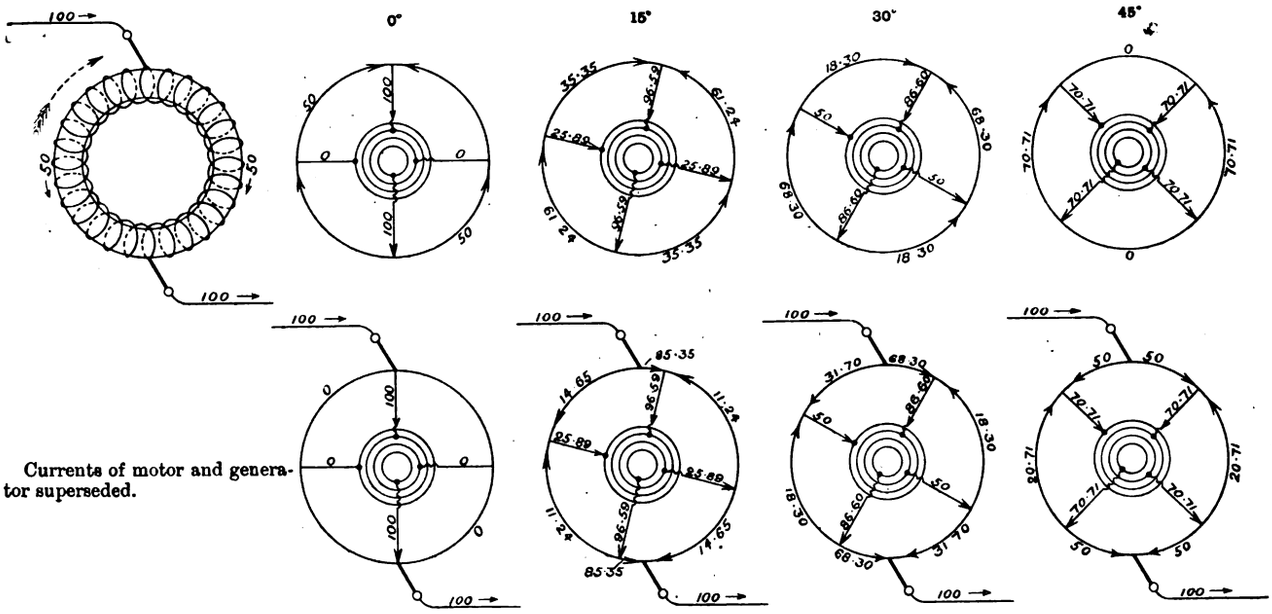

FIG. 7.—Flow of Currents in Two-phase Converter. Continuous Current, 100 amperes at 100 volts. Two-Phase Currents, 4 lines each carrying 70·7 virtual amperes. Line voltage, 50 virtual volts.

104 amperes as the motor current: in position 0deg. the two downward currents would be 52 each instead of 50, increasing the positive acceleration; in position 90deg. the upward currents would be 48 instead of 50, decreasing the negative acceleration. The output current at that instant would still be 200, being made up of 104 incoming plus 96 generated in the windings.

On further examining these diagrams it will be seen that the currents in the armature windings consist of a set of four currents, would obtain in either armature of the motor-dynamo machine (Fig. 3). This unequally distributed heating effect is in total somewhat greater than that in the same armature if used purely as a continuous-current motor or generator, but is less than the total heating effect (for equal power) if used purely as single-phase generator or motor; the ratios of the heating being as 1 : 1·366 : 2 in the three cases. Or, if we consider the output of an armature to

* *Vide* Steinmetz, *loc. cit.*, p. 154.

Digitized by Google

be limited by equal heating effects, the several outputs which would give equal total heating in the same armature would be:—As continuous-current generator or motor only, 100 kilowatts; as single-phase generator or motor only, 50; as single-phase converter, 85 kilowatts. Fig. 6 exhibits this unequal heating effect in the case of a single-phase converter. The first line represents graphically by the outline diagram the varying current (irrespective of direction) which a coil midway between the connectors will carry in one revolution; and the outline curve of the darkened area within it is drawn with ordinates squared so as to be proportional to the heating effect at different instants. The total area blackened represents the total heating effect in that coil. The second line represents similarly the current and heating for a coil 30deg. further towards the connector. The third line represents current and heating for a coil 60deg. further, whilst the fourth line represents similarly the current and heating in a coil that is next to the connector. The relative heatings in these four coils are about in the proportions 10, 21, 50, 86. The curves in the fifth line depict the case of one of the coils next to a connector when there is, in consequence of self-induction in the circuit, a lag of 30deg. in the phase of the current. The result of such phase-difference is an increase of heating for the whole armature, but an extra increase for those coils which are near the connectors.

We may now pause to consider what differences will be made in the preceding considerations if the distribution of the magnetic flux around the periphery of the armature does not follow a sine law. It will be noticed that when any arc of the winding (and this applies to two-phase and three-phase cases) lying between two slip-ring connectors is acting as generator, it produces its greatest electromotive force when its mid-point is passing the mid-point of any pole. Hence, if the poles are narrowed so as to concentrate the field, even though the average electromotive force for continuous-current purposes remains unchanged, the root mean square value of the electromotive force will be increased, and the curve of induced electromotive forces will be more peaked than a sine curve. If the machine is being used to convert continuous current into alternating, the effect will be to raise the relative alternating voltage and lower the relative alternating current, and, on a non-inductive circuit, the current also will have a more peaked curve. If the machine is being used to convert alternating into continuous currents, the converse result takes place, the relative value of the alternating voltage being lowered. An eight-pole converter at the Technical College, Finsbury, constructed in 1891 by the Allgemeine Elektricitäts Gesellschaft, of Berlin, has a curve of induction which is remarkably close to a sine curve, and its relative voltage for continuous and three-phase currents is practically identical with the theoretical value. Herr Friese, in the article already referred to, gives the following comparison in Table V. for three machines with ring armatures constructed by Messrs. Schuckert:—

Table V.

Nature of service.	Voltages as measured.			Voltage calculated.
	Machine No. 1.	Machine No. 2.	Machine No. 3.	
Continuous-current ...	100	100	100	(100)
Single-phase	71·0	71·8	..	70·7
Three-phase.....	61·3	62·0	61·8	61·2
Two-phase	71·0	71·8	...	70·7
Four-phase	49·8	50·7	...	50·0
Six-phase.....	35·0	35·8	...	35·4

M. Hanappe* has published a careful analysis of a Schuckert converter, capable of yielding alternating currents in one, two, three, four or six phases, and suitable for laboratory experiments.

If the machine is being used to convert a single-phase current into a continous one, the form of the impressed voltage curve, and the distribution of the flux around the periphery, are of even greater importance. The current delivered, though certainly continuous, will not be uniform, but will have a periodic fluctuation superimposed upon it by departures from the sine law. Armature reactions will, as we have seen above, impose fluctuations of a frequency double that of the primary current. Indeed, in any case the single-phase converter is a less satisfactory apparatus, from several points of view, than the two-phase or the three-phase converter. It has more considerable variations of armature reaction, a greater and more unequable heating, and requires a more accurate setting of the commutator brushes than the polyphase converters. Moreover, it is not self-starting from the alternate-current side. Notwithstanding these disadvantages, single-phase converters are in satisfactory use; for example: several constructed by the Elektrizitäts-Aktiengesellschaft (Schuckert and Co.) are in operation on the city circuit at Cologne. A single-phase converter when standing still can act partly as a mere stationary transformer. When running at a certain speed in a field with a given number of poles it will act as converter, converting into continuous current those currents only which come to it with a frequency corresponding to the frequency of the movement of revolving conductors past the poles. Any alternating currents or components of alternating current of any other frequency that may be superposed, can affect the continuous-current output at the other side by producing superposed fluctuations.

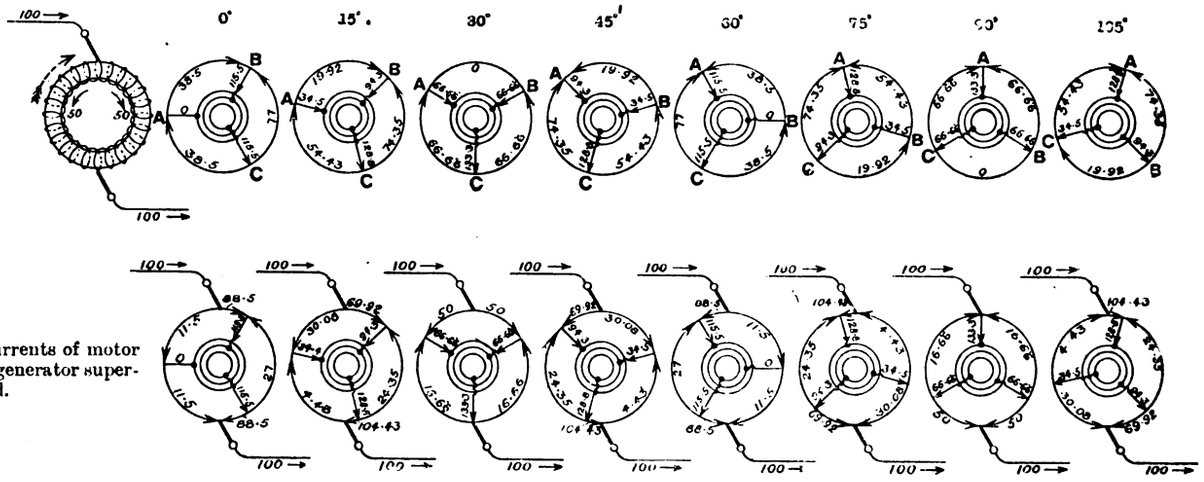

FIG. 8.—Flow of Currents in Three-Phase Converter. Continuous Current, 100 amperes at 100 volts. Three-Phase Current, 3 lines, each 94·3 virtual amperes; line voltage, 61·2 virtual volts.

Passing on, then, to the case of the two-phase converter, we may at once apply the same principle of superposition of instantaneous currents to study the flow of current through the windings. Fig. 7, which gives the corresponding series of diagrams, requires no further explanation. The generator action during one-eighth of a revolution is illustrated by the four figures on the right of the upper line. The superposed action is exhibited in the lower line. Inductive reactions and energy losss are, as before, supposed to be absent. In position 0deg. the converter is acting neither as motor nor as generator, the current at that instant simply running through from the commutator to the slip-rings. In the position 15deg. it is observed that the currents in the armature windings consist of six sets. Two short portions are carrying a motor current of 85·35 amperes each; two others of somewhat longer arc are carrying a motor current of 14·65 amperes; whilst two quadrantal parts are delivering generator currents of 11·24 amperes. On the whole, in this position the armature is acting as motor, increasing the acceleration. In the next position, at 30deg., the motor action has decreased. In the position at 45deg. the action is chiefly generator, the current in that part of the field which is strongest being at its maximum and flowing with the electromotive force. It will again be noted that the currents in those coils of the armature which lie close to any of the four connectors will be more heated than those midway along the intervening quadrants; the maximum current for the former being 100, for the latter 50. The inequality of the heating is much less, however, than in the single-phase armature. Also armature reactions are more nearly balanced throughout, and there is much less tendency to impart a periodic fluctuation to the continuous current. Such machines will

* *L'Eclairage Électrique*, VIII., 151, July 25, 1896.

Digitized by Google

be self-starting, and will give little trouble from sparking at the commutator.

Fig. 8 exhibits the flow of currents in the armature of a three-phase converter. Comparison of the successive positions will bring out several points. The current in any one of the three lines is at its maximum (on a non-inductive circuit, when generator; or when, as motor, the field has normal excitation) when the connector for that line is just passing a commutator brush; and its maximum is $1\frac{1}{2}$ times the continuous current. In certain positions of symmetry—for example, in position 30deg.—the motor and generator actions resulting from the flow are bilaterally similar. In other position—for example, in position 0deg.—one side (the left here) is acting wholly as motor, the other side partly as generator and partly as motor. A coil which lies midway between two connector ends will carry a current that has a maximum of 27 in one part of its revolution, and another maximum of 50 in another part of its revolution; there being two of each of these maxima in one revolution. A coil situated close to a connector has 133·3 as its maximum twice in each revolution, with an abrupt change to or from 16·66 just as it passes the brush. The inequality of heating of coils is less in a three-phase converter than in a single-phase, but it is greater than in a two-phase converter. The inequality of heating in the case of two-phase converters has recently been examined analytically by Messrs. Woodbridge and Child in recent numbers of the *Electrical World* (January 1 and February 12, 1898). Their Paper, which is one of great skill, concludes with the interesting deduction that, assuming a power factor of unity, if such a converter is driven mechanically so as to be generating *both* a continous and a two-phase current at the same time, the heating of the armature will be less than would be the case if, with same output, it were used as either a continuous-current generator alone or a two-phase generator alone.

(To be concluded.)

THE RAPID DEVELOPMENT OF ELECTRICAL ENGINEERING DURING THE PRESENT YEAR.

The following is an abstract of the Presidential Address, recently delivered by Mr. G. S. Raworth to the Northern Society of Electrical Engineers:—

The Northern Society of Electrical Engineers, measured by its numbers was small and insignificant, but measured by its activity, by the energy and enterprise of its members, it was, he believed, the first electrical society in the Kingdom. It was because the members had been so very full of work during the present year that the Council had found it extremely difficult to get the members to prepare and to promise papers for this session: in fact, so great was the difficulty that, although they were able by the assistance of Members of Council to fill up succeeding dates, it was found quite impossible to carry out the intention of the Council that the first Paper of the Society should be read in October.

He first of all proposed to run lightly over the departments in which the development had been more or less strongly marked. The first thing that naturally arose in the mind was the department of electric lighting. He was not going to trouble them with many figures, but must give them a few, because they were so interesting that he did not think they would like to go away without knowing them. In the year 1896 the subscribed capital for companies was £5,800,000, and for municipalities just under two millions. In 1897 the companies went to £6,600,000, and municipalities to £3,500,000. In 1898 companies jumped up by nearly two millions, and municipalities by a rather larger amount, *i.e.*, to £5,735,000, so that at the present moment the total amount of capital involved in electric lighting was £14,142,000. A most important point was that in the years 1882-3, which were known as the years of the electrical boom, the total amount of capital subscribed was £14,743,000. If they had only taken care of the money which the public subscribed in those two years, we should never have had to ask for a single penny more in the whole of the 15 years which had since elapsed. Coming to the present year, they found that the activity in electric lighting was very pronounced. There were in 1896, 38 applications for Provisional Orders; in 1897, 55; in 1898, 84, the total Orders in force being 343—100 held by companies and 243 by municipalities. There were works in operation owned by 57 companies and 75 local authorities, and 66 works were in course of preparation. He wished to draw attention to the important fact that 145 Provisional Orders had been granted, concerning which nothing whatever had been done. There was no doubt but that in most of those cases the ground was ready for the ploughshare. There was a point of interest which he had noticed in analysing the figures; he found that out of every £100 applied for the purposes of electric lighting, £37 went to the manufacturer of plant and £34 per cent. to the manufacturer of mains. Manufacturers of plant made all the noise and held all the meetings, and, as far as he could see, the manufacturers of cable made the profit. In 1897 the total number of units sold was 60,125,000, and a curious point about that was that the whole of that current could have been produced by no more than 20 1,000 kilowatt sets working during factory hours, but the actual amount employed was not less than 72,000 kilowatts. The human mind always found a difficulty in dealing with small or large figures. The moment they got into millions it seemed as though the mind could not quite grasp what was talked about. They might think that, because we had got 14 millions in the electrical industry, that we had pretty well absorbed all the capacity of the English shareholder. But compare electricity with gas; the total capital employed in gas was 76 millions, and they spent as much every year upon making their gas as the total subscribed capital of the electrical industry—*i.e.*, $14\frac{1}{2}$ millions.

The next point to consider was that of electric propulsion. As he had told them last Christmas, they had in all about 133 miles of tramway working. Owing to Parliamentary preliminaries to be gone through, plans to be got out, and capital to be subscribed, there had been very slow progress. They had only added a matter of about 40 miles to the total of last Christmas. There were under consideration at the present moment 39 miles by municipalities and 45 miles by companies. In the session of 1898 five electric railway bills were passed, 17 tramway bills for local authorities and 10 for companies, and 11 Provisional Orders, in addition to which light railway Bills had been granted for 140 miles of line. When they came to actual figures, they found that the amount of subscribed capital was £14,400,000, being about £270,000 more than the subscribed capital for electric lighting. He thought this high figure was partly owing to the initiatory expenditure on schemes, and partly owing to the large and expensive undertakings which were being carried out in London to connect the suburbs with the City by means of underground tunnels. Every mile absorbed nearly half a million pounds, so that the amount of capital subscribed for that alone had gone very far to produce the figure of £14,400,000. The unfortunate part about it was that the money did not go into their pockets, or, at least, only a very small percentage of the money subscribed for underground railways ever reached the pockets of electrical engineers. It went to the engineers of Westminster, or to the contractors for underground work. There were one or two other developments in propulsion which he had to speak about, but which were not quite so hopeful from their point of view as those which he had already mentioned. The first was the propulsion of boats, and as far as he knew the only active company was the Immisch Company on the Thames, which owned a large number of launches, having a capital of £10,500, and which paid a small dividend. He himself was one of the Directors. He was looking forward to that class of propulsion developing somewhat in the future. Electric launches were tried on Lake Windermere, and they were probably aware of the fact that the undertaking was a comparative failure. He wanted to disabuse their minds that that failure was due to the shortcomings of the electrical portion. It was entirely due to the human element. The undertaking had been badly planned, so that the boats had to go several miles to be charged, and several miles back again to their work. The consequence was that the actual available net charge was below the paying limit. The next point which he would bring before their notice was the electric cab. He wished he could tell them that the electric cabs were going to be a great success. Their number had been very greatly increased, and he understood they worked very well, and as far as passengers were concerned he believed they gave every satisfaction. How the accumulators were working he could not tell.

The present year had been a very important year to them from the point of view that a Lords and Commons Committee had been appointed to sit upon the general question of electrical distribution of power. First of all, they passed two Bills, the Chelsea Company's Bill to enable them to purchase compulsorily a site within their own area; that was an enormous step in advance of anything that had been previously done. The next one was the Metropolitan Company's Bill to enable them to lay mains outside their area, and to bring current in. That was a still further and a more drastic change. It enabled a company supplying a given area to put its generating station right outside that area, and to get wayleaves across the territory of adjoining authorities for its mains to enter its own area. Then the joint committee passed its opinion as follows upon the general principle of the distribution of power. First they expressed the opinion that powers should be granted for the supply of electrical energy over an area including districts of numerous local authorities on conditions differing from those imposed by the existing Acts. Differing meant better. Secondly, they expressed the view that the provisions of the Electric Lighting Acts for the purchase by local authorities were inapplicable in the case of an undertaking

Digitized by Google

supplying energy in bulk at a high voltage. Those expressions would prove most valuable in the coming session of Parliament The Bills now before the House were the General Power Distributing Co., which they knew was going to take a large area in the neighbourhood between Nottingham and Sheffield, an area of about 2,000 square miles; the Midland Electric Co. for power distribution, whose area was in the black country, and who had a capital of £200,000 on paper. Those two were magnificent schemes. Whether they were well thought out and going to pay he was not prepared to say, but they owed a debt of gratitude to them because they squeezed out of the Lords Committee those two very important concessions. They had in their midst, as it were, a scheme which he thought would commend itself not only to them but to all electricians and engineers throughout the country, as being, perhaps, the most practical development of this idea that had yet come out. He referred now to the Trafford Park Estate scheme. That was an undertaking that had been favoured by Messrs. W. T. Glover and Co., who were promoting it, and, so far, finding the money for it. The object was to supply power in bulk for driving all the factories, lighting the factories, and for supplying producer gas to the houses on the Trafford Park Estate. That was a perfectly feasible scheme. It was one of which every engineer could form an opinion from the commencement, and it would be the nucleus of a much larger development. The engineers to the scheme had told him that they originally looked upon his figures of the price at which electrical energy could be manufactured and sold with considerable doubt. They set to work and worked out those figures upon their own lines, and for their own satisfaction, and they found that the results of his calculations and theirs came out sufficiently close for all practical purposes. There was at the same time that scheme called the Highland Power Scheme of Scotland, of which he could give them no further information. As to the general distribution of power in factories, that was making very satisfactory progress.

The electrical chemical industry, that was one of those things which he did not understand, but he believed it was making very good progress. It must be patent to every one of them that the Castner-Kellner process of making alkali by electrical energy had proved so far a success. There was one other point came to his notice, and that was the new process of reducing ores by powdering aluminium, making it up with ore, and igniting the mass electrically, when chemical energy would be immediately let loose and propagated through the whole mass, and heat generated being nearly equivalent to that of the electric arc. The immediate effect was the reduction of the metal operated upon. If that invention proved a commercial success, it would open an enormous field for the use of aluminium, and consequently for the use of electric current.

He ought now to consider what were the causes which were working towards the extension of the use of the electric current. They knew perfectly well whenever an electric lighting station was put down, and worked well or badly, its customers increased, the revenue increased, and the profit increased, and the most natural thing which he could do was to give them a few figures to show what that development amounted to. He had taken as illustrations four stations which had suffered very little from alterations in price, viz., City of London, Newcastle, Kensington and Chelsea, and he found that with those, with the exception of the year 1894-5, when the increase in the City of London was 48 per cent., the increase from year to year had been about 25 per cent. The year 1895-6 was a phenomenal year. The City of London increased 43 per cent. and Chelsea 41 per cent., but both these places were subject to peculiar circumstances. The extension of Chelsea had been almost entirely depending upon the rate at which the builders spend their money. However, they might take it, he thought, that the natural increase, was somewhere about 52 per cent. The next point was one of much more importance to them. That was a question of how far the cost of plant and the cost of working affected their business. A few years ago (about five or six), the cost of a 100 kilowatt plant, rope driven, was £1,600 to the public. Now the price for a direct-driven plant was from £1,300 to £1,400, but in the meantime either our faith or ideas had grown so much that no longer did we talk about 100 kilowatt sets. Last year the inquiries were for 300 kilowatts, this year they were for 600 kilowatts, and he understood Manchester had gone to 2,500 H.P. A 600-kilowatt plant was worth about £6,000, and six plants of 100 kilowatts each would cost £9,600, so that there was a saving of £3,600. If they put on to the top of that the saving in switchboards, land, foundations and buildings, they came to the fact that at the present day the cost of plant should not be more than about 60 per cent. of what it was five or six years ago. He thought to a very large extent their efforts had been stimulated to take those big leaps by the clear understanding that those enormous wastes which were supposed to accrue from running engines at half load could be obviated by a good vacuum and automatic expansion. With reference to the working of stations it was worth while putting upon record the fact that, whereas four or five years ago they did not think it at all an extravagant thing to spend 5d. a unit, now they had 14 stations whose total costs (not meaning the absolute cost of the unit) was under 2d. In Edinburgh the cost had just come under 1¼d., and in Manchester it was about 1½d. As the cost came down the demand increased. The moment they got the prime cost to such a point that they could sell to the ordinary consumer at a price which was obviously to him less than the price of gas, they would sweep in the whole number of possible consumers which they could supply.

The next point was "Parliamentary Procedure," which at present was both tedious and costly. There was not a great prospect of their getting much amelioration in that line, but they might get some, the recommendations of the Lords and Commons Committee and the provisions of the Light Railways Acts being distinctly favourable to the progress of the electrical industry.

He had down on his list of principal influences, which affect the rate of progress, an item under the heading of "Avarice of Municipalities," and he had limited it to this narrow word "avarice," because he did not want to go into the discussion of the question as to whether from political reasons it was an advantageous thing for municipalities to take over and manage their business. Electric lighting was too young to provide a good basis of comparison; the results were contradictory, and at present too much under the influence of the personality of the engineer to permit of accurate conclusions being drawn from them; but municipal gas lighting was quite old enough for the purpose, and the results could be compared by reference to two large volumes, which were the Board of Trade returns of the gas undertakings in the United Kingdom, one representing companies and the other municipalities. There were 208 municipalities and 433 companies owning gasworks.

First, consider Manchester, a city which manages its gas works nearly as well as they can be managed by a Corporation. The price is 2s. 3d. per thousand, and the profit is £33,153 interest and £40,000 in aid of the rates—total £73,153. On the other hand, the South Metropolitan Gas Co. charges its consumers the same price and makes four times the profit, or double the output—that is, twice the profit *pro rata*, notwithstanding that it has to pay heavy carriage on coal. Again, compare Manchester with the Sheffield United Gas Light Co., the two cities being nearly on a par as to cost of coal. The price of gas at Sheffield is from 1s. 8d. to 2s.; the consumption is about one-half of Manchester, and the profit is £78,829—that is, more than double *pro rata*. If the Sheffield Corporation were to authorise the Company to charge the Manchester price of 2s. 3d. they could afford to pay over £42,000 in aid of the rates at the expense of the consumer; or, if their output were as large as that of Manchester, they could pay over £80,000 a year in aid of the rates and still pay to their shareholders £140,000 per annum, as against the £33,153 paid for interest in Manchester. But assuming for the moment that the results in Manchester were as perfect as in Sheffield, the amount handed over in aid of rates would be not £40,000 but £80,000 + (140,000 − 33,153) = £186,847. In Birmingham, with equally cheap coal, their price is from 2s. 3d. to 2s. 7d. with 5 per cent. discount, and yet they desire to manage their electric lighting. Take two towns as dissimilarly placed as possible—Wigan and Plymouth. Wigan is built on gas coal; Plymouth is hundreds of miles from it. Wigan Corporation charges 3s. 1d.; Plymouth charges 1s. 9d.; but in this instance Wigan pays in aid of rates £9,697, but the difference between their price and that of Plymouth on their output amounts to £6,600, so it is clear that, considering the relative prices of coal, they are taking the whole of their apparent profit out of the pockets of their gas consumers, that is to say, of their ratepayers. Again, compare two gas undertakings placed side by side and subject as nearly as possible to identical conditions—Stoke-on-Trent Corporation and the British Gas Light Co. (Potteries). The Corporation price varies from 3s. 6d. to 2s. 9d., but the Company's price is only 2s. 3d.

Electric traction and electric distribution of power were being pushed on by private enterprise, and he hoped that this active private energy of theirs would not be entirely killed by municipal obstruction. There was one point which was always before them, and that was foreign competition. He was not afraid of it; in fact, it appeared to him that, at the present moment, it was a good thing that it was possible to get plant from America, because, had it not been for that fact, electrical enterprise in the year 1898 would have been suffering from great strangulation. Speaking from his own knowledge alone, the Central London Railway Co. had ordered, he believed, seven sets of 1,400 H.P., the Metropolitan three of 2,500, and the County of London two sets of 1,000, all manufactured in the States and sent over here; but he knew that, with regard to some of them, if they could have been made in this country in the time the order would not have been given to the States. It came down to this fact, that the Americans were not competing with us at our prices; they were only supplying those orders which could not be done in this country.

PHYSICAL SOCIETY.

At an ordinary meeting, held on November 11, 1898, Mr Shelford Bidwell, F.R.S., President, in the chair, the discussion was resumed on Mr. ALBERT CAMPBELL'S Paper on

"The Magnetic Fluxes in Meters and Other Electrical Instruments."

Prof. AYRTON said he wished to offer some remarks on behalf of Mr. Mather and himself. The Paper would perhaps have received more adequate discussion at the Institution of Electrical Engineers, for it was of a technical character. The importance of neutralising the effect of leads when using instruments with very weak fields, such as a Siemens electro-dynamometer, should be emphasised. In instruments of the Kelvin-balance type, where two opposed coils carry two opposed currents, the field spreads at the edges; the true "working" flux is not that directly between the coils. Mr. Campbell would have done better if he had used a long search coil wound round one of the swinging coils, forming part of a vertical cylinder. It would have been well also to have supplied some experimental proof that the astatic arrangement of the swinging coils of the Kelvin balance makes the instrument independent of the earth's field. The effect of the earth's field is of the order 0·2, so that with instruments of the Weston type, with a field of the order 1,000, it was sometimes assumed, erroneously, that the readings were practically independent of the earth's H. Prof. Ayrton's own tests showed that by turning a Weston voltmeter towards different points of the compass, the errors in a particular case were far greater than might be predicted from the above ratio; the induction in the voltmeter pole-space, due to the earth's field, was much higher than 0·2; the earth's field was exaggerated by the iron pole-pieces; it was not necessary to suppose that the magnetism of the permanent magnet caused the variation. The error observed was about 0·2 per cent. in a horizontal field, and 0·8 per cent. when the field of the voltmeter was parallel to the earth's induction. Here the induction in the gap was 1,200, and H = 0·2. In tests relating to the Ayrton and Perry magnifying-spring voltmeter, it was more important to know the B in the air-space *near* the iron than the B *within* the iron. Eddy currents might account for the extraordinary results obtained with the Shallenberger meter.

Mr. J. H. REEVES described a method he had adopted for measuring the effect of stray fields upon ammeters and voltmeters. The instrument to be tested is first mounted on a stand, and is brought under the influence of a large coil carrying a current. In this way, fields of known magnitude can be superimposed on the working field, throughout the range of the instrument, and the change of deflection due to them can be observed. From these known values, the working field can be deduced. For let the current in the solenoid of the instrument at any moment be A amperes, producing a corresponding unknown working field of magnetic force X. Then X is proportional to the solenoid current, as measured by the indications of the instrument. If a magnetic force, x, is superimposed on X, then x is measured by x/X of A. If x is known, the working field X can be calculated from the change of deflection produced by the superposition. With Evershed ammeters, the field measured in this way was in one instrument 200, and in another 226; or about one-third of Mr. Campbell's figure (700) for the Evershed ammeter. Mr. Campbell's value of B did not represent the working field, but the field at the end of one of the fixed pieces of iron.

Mr. CAMPBELL, in reply, said he thought the theory of electrical instruments to be well within the limits of Physics, and he had for that reason presented the Paper to the Physical Society. The position chosen for the search coil in the Kelvin-balance tests may not have corresponded to the working flux, but it was near to the right position, and he had carefully specified the position chosen. His results as regards the Weston instrument differed from those of Prof. Ayrton; the errors he had observed for the particular ammeter used were under 0·1 per cent. The earth's field probably produced an effect different for different Weston instruments, according to the degree of saturation of the permanent magnet. In Mr. Campbell's tests, the Weston instrument did not have an iron case.

Prof. J. D. Everett then read a Paper by Prof. W. B. MORTON on—

'The Propagation of Damped Electrical Oscillations along Parallel Wires."

In a Paper published in the *Phil. Mag.* for September, 1898, Dr. E. H. Barton compared the attentuation of electrical waves in their passage along parallel wires, as experimentally determined by him, with the formula given by Mr. Heaviside in his theory of long waves. He finds close agreement as regards the effect of a terminal resistance, but large discrepancy in the case of the attenuation-constant. Prof. Morton now investigates how far the results should be modified when it is supposed, as under actual conditions, that the oscillations propagated from the origin are damped, and that the circuit is not balanced, as in the ideal case of distortionless transmission. He finds (1) that the velocity of propagation is increased, while (2) the attenuation is increased, and (3) with infinite resistance between the ends of the wires, the waves are, as before, reflected completely with phase unchanged. As the resistance is diminished the amplitude of the reflected waves is decreased, and a phase-difference is introduced. For a certain value of the resistance the reflected amplitude is a minimum, and the phase-difference is $\pi/2$. When the resistance is zero there is again complete reflection, with phase difference π; *i.e.*, the waves are reversed. The result is that the reflection factor for amplitude *seems* to pass continuously from $(+1)$ to (-1) *without* passing through zero. Using the numbers given by Dr. Barton it is found that the corrections to the simple theory are extremely small, so that in actual cases the damping may be ignored, and the circuit may be regarded as distortionless.

Mr. OLIVER HEAVISIDE (abstract of communication), using his own notation, exhibited mathematically the connection between the case investigated by Mr. Morton, of a wave-train arising from a damped source, and the standard case of an undamped source. The cause of the attenuating coefficient coming out twice as great in Dr. Barton's experimental conditions, as when the resistance is calculated by Lord Rayleigh's formula, he attributed to lack of correspondence between the experimental conditions and those of the ideal theory. For: (1) The external resistance, of unknown amount, is ignored. (2) It is not certainly to be expected that the formula in question is true for millions of vibrations per second. It may, however, be concluded from the experiments that the theory furnishes an approximation to the real resistance. (3) The magnetic vibrations to which the wires are subjected are not long continued and undamped, as assumed by the formula. When a wave train passes any point on a wire its surface is subjected to an impulsion vibration lasting only a very minute fraction of a second; a vibration, moreover, which is very rapidly damped. So there is no definite resistance, and the resistance is greater than according to Lord Rayleigh's formula. (4) Perhaps, also, the terminal reflections involved in Dr. Barton's calculations may introduce error.

The PRESIDENT proposed votes of thanks to the authors, and the meeting was adjourned until Nov. 25.

REPORT OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE COMMITTEE ON STANDARDS OF MEASUREMENTS.*

The determination of the mechanical equivalent of heat by the electrical method, as reported by Griffiths,† and by Schuster and Gannon,‡ gave a larger value than Rowland's corrected result. This fact has created a demand for the redetermination of the ampere in terms of the electro-chemical equivalent of silver. At the Toronto meeting of the British Association last year a grant was made to the British Association Committee on Electrical Measurements for the purpose of carrying out this investigation.

At the Detroit meeting of this Association the grant of 50dols. previously made for the use of this committee was made available for the past year. Though this appropriation was clearly insufficient for the purpose, it was decided that the redetermination of the ampere should be undertaken for the committee of this Association in the physical laboratory at Ann Arbor. The work has been ably carried to completion by Prof. Patterson and Dr. Guthe.

The discrepancy between Griffiths' results and those of Rowland is about one part in 400 at all temperatures between 15deg. and 25deg. on the nitrogen scale. Those of Schuster and Gannon exceed Rowland's at 19·1deg. on the same scale by about one part in 500.§ These differences exist after the final elaborate comparison of thermometers and the reductions to the same absolute scale of temperature.

Since the electrical methods employed to determine the mechanical equivalent of heat involve either the current and the E.M.F. of the Clark cell, or the square of this E.M.F., and since the E.M.F. of the Clark cell is determined by means of the silver voltameter, it is evident that the current enters the final result as the square. If the discrepancy is due entirely to an error in the value of the ampere, assuming the ohm to be correct, then the ampere should be one part in 1,000 to one part in 800 larger than the present accepted value. That is, the electro-chemical equivalent of silver should be increased from Lord Rayleigh's value of 0·001118 to 0·0011191 or 0·0011194. Lord Rayleigh does not claim for his result an accuracy greater than one part in 1,000.

The method used by Patterson and Guthe was that of a specially constructed electrodynamometer of large dimensions, and the employment of the torque of a phosphor-bronze wire to equilibrate the counter-torque due to the effort between the magnetic fields of the stationary and movable coils. This method eliminates entirely the value of gravity g. The torque of the wire was measured by observing the period of vibration of a cylindrical brass weight of known mass and dimensions when suspended by the phosphor-bronze wire. The entire success of this part of the investigation was due to the fact that the observations were made with the whole apparatus enclosed in a fairly good vacuum. Under these conditions the vibrations could be followed for hours at various inter-

* Presented by Prof. Henry S. Carhart, secretary of the committee.

§ John Hopkins University Circulars, June, 1898.

Digitized by Google

vals ; the logarithmic decrement was almost entirely constant, and it was easy to obtain a curve connecting temperatures and periods of vibration as a torsional pendulum. The wire was so connected to the support and to the brass cylinder that it could be transferred from the vacuum apparatus to the electrodynamometer and back again without disconnecting it from the terminal pins. From personal inspection at the several stages of the investigation assurance can be given that the work has been most carefully executed at every point, and all known sources of error have been as completely eliminated as possible. The result of the investigation is that the electro-chemical equivalent of a used solution of neutral silver nitrate, 15 parts by weight of the silver salt to 85 parts of distilled water, is 0·0011192 grammes per ampere per second. This exceeds Lord Rayleigh's value by about one-ninth of one per cent. and causes the discrepancy in the mechanical equivalent of heat to disappear.

The corresponding change in the E.M.F. of the Clark cell will be from 1·4342 to 1·4372 at 15°C. A direct termination has not yet been made and this redetermination is reserved for the coming year. Dr. Kahle has obtained for the electro-chemical equivalent of silver the value 0·0011182* by the use of an electrodynamometer designed by Von Helmholtz and a fresh solution of the salt. Pellat and Potier found the same value as that of Patterson and Guthe.†

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November 4, 1898.*

Peace Jubilees.—The week before last a peace jubilee was celebrated in Chicago, and last week a similar celebration took place in Philadelphia. The chief features of the celebrations were the night illuminations, in which, of course, the electric light was predominant. In Chicago 50,000 extra incandescent lamps, at the lowest estimate, were burned in the streets. The plan adopted of decorating the downtown districts consisted of making a roof of flags by day and of light by night. The flags and lights were strung in rows at regular intervals across the streets, the lights swinging in graceful festoons above the centre of the roadways to the buildings on either side. Over three miles of streets were decorated in this manner, and upwards of 10,000 16 c.p. incandescent lamps were employed. The work was done by the Chicago Edison Co., and was completed in two weeks after the signing of the contract, over 100 men being employed on the task. The lights were turned on every evening at 6:30 o'clock, and extinguished at 11:30. The system of decorative lighting took about 2,500 amperes at 220 volts, supplied by the Edison central station. Next to the festoon lighting the principal feature of the jubilee was the municipal arch donated to the city by the Western Electric Co., the General Electric Co., and the Chicago Edison Co. The structure was 45ft. high and 50ft. wide, and was lighted by 1,200 lights set in porcelain wall sockets arranged 15in. apart on strips of wood fastened to the arch in 8ft., 10ft. and 12ft. lengths. The entire 1,200 lights were put in place, wired up and connected in 24 hours. The arch was connected with the City Hall plant, which furnished the current by a 300ft. overhead line consisting of three No. 0000 B. & S. cables. The cost of the lighting for the peace jubilee is estimated to have been between £6,000 and £8,000. At the Philadelphia jubilee the principal feature was a similar arch and a colonnade of 28 columns illuminated by 5,000 incandescent lights. The arch was 80ft. long and 45ft. high and was constructed of wood and finally covered with plaster previously made in sections from the design. Feeders were carried from the underground mains of the Edison Electric Light Co. in iron pipes laid along the gutters on each side of Broad-street, and branch circuits for the columns were carried by the shafts on the outside. Current for the illumination was supplied by the Edison Electric Light Co. from its Sansom-street station for five hours on each of the three nights of the celebration. As the extra load upon the station came after the peak of the load, no extraordinary arrangements were necessary for power, the regular equipment supplying all that was needed for the occasion.

Electric Tanning Processes.—At the meeting of the Electric Potential Club in Boston, on the evening of October 26, Mr. George D. E. Burton illustrated and described by the aid of lantern slides the various apparatus and processes employed in tanning by electricity. The process of unhairing hides is effected by means of a vat or tank containing a suitable solution in which the hides are suspended and through which the current is passed by means of electrodes partially immersed therein. Screens are provided to protect the hides from actual contact with the electrodes, and there are also means for agitating the liquid. The effect of the current is to raise the hair from the skin and thus render the hair porous as well as more accessible to the action of the solution than was the case with the existing methods. Mr. Burton explained that the comparative rapidity of the electric treatment did not injure the leather. The tanning process was substantially similar as to apparatus and procedure, a suitable solution for the purpose, of course, being employed. The operation of the current, Mr. Burton considered, was mainly to open the pores of the material, thus affording the tanning solution better access thereto. Among the principal advantages claimed for the process are saving of time involved and consequent tying up of capital ; some improvement in product and a considerable reduction in space occupied, as the tanner using the electrical process may dispense with at least one-third of his vats. As to the actual saving in dollars and cents, information was meagre at present, but in one instance it has been found that there was a saving of 8d. on every 60lb. hide, as compared with the ordinary methods of tanning.

The Third Avenue Railroad Co.—Last Monday this company commenced the preliminary work of introducing electric power on its various lines in this city. The principal lines of the company are now operated by cable and the minor roads by horse. The underground conduit system will be installed on all lines and the work will be carried on as rapidly as possible. The company some time ago built a large power station at the upper end of the city, which has ever since been lying idle. It is proposed to equip this station with the most modern generating machinery of the alternating type and distribute high tension currents to various sub-stations throughout the city, where the current will be transformed to lower potential for the operation of the cars.

The John Stephenson Co.—This well known street car builder of this city has applied to the Court for permission to dissolve the corporation and for the appointment of receivers. Messrs. Albert A. Wilson and Louis Stern were appointed receivers. The petition states that the company cannot meet its maturing obligations. The company is carrying out a number of important and valuable contracts from which, if they can be completed, considerable profit can be realised which will be of benefit to its creditors.

Calcium Carbide Furnaces in Canada.—A new industry has been established in Ottawa, Canada. It is the manufacture of calcium carbide for the production of acetylene gas by means of a new—yet simple and effective—method. The inventors are Messrs. H. Lamoth and J. W. McRae, of Ottawa. The novelty lies in the furnace itself, which consists of two electrodes, one suspended above, and the other placed on the ground. The two are connected by means of carbon pencils which form an arc, producing sufficient heat to melt the coke and limestone which are piled around the electrodes, and form it into calcium carbide. It is the intention of the promoters of this new industry to erect a plant of forty furnaces which will be kept running 16 hours a day. Carbide is produced for £12 a ton wholesale, and the factories now manufacturing this product throughout Canada are unable to keep up with the orders.

The American Asiatic Association.—Many of the largest producing concerns in various lines of trade have organised an associatien under the above-named title, for the purpose of disseminating among its members all the information touching matters pertaining to trade with Asiatic countries, including China and the Philippines. Among its members are such concerns as the General Electric Co., the Okonite Co., the Westinghouse Electric and Manufacturing Co. and many others of equal standing in different branches of industry.

LEGAL INTELLIGENCE.

Holophane (Limited) v. O. Berend and Co. (Limited).

Mr. Justice Kekewich heard this action on Tuesday.

Mr. JESSEL (for plaintiffs) said the action was for infringement of patent, and at the last moment defendants had agreed to submit to an injunction and pay costs, plaintiffs waiving their claim for damages. He asked his lordship to issue an injunction and for two things besides: first, a certificate that the plaintiffs' particulars of breaches were reasonable and proper; and, secondly, a certificate that the validity of the patent had come into question.

Mr. Justice KEKEWICH: I am bound by the authorities.

Mr. JESSEL submitted that the authorities were in favour of granting the certificates. Defendants admitted that they did threaten, and did intend to put on the market, a globe which they now admitted was a breach of the Holophane patent. In the present case defendants, by appearing by counsel and admitting the plaintiffs' rights to an injunction, admitted that there were breaches. When the defendants not only did not run away, but fought you and only gave in at the very last minute—the case was settled only an hour or two before—in order to save expense, the Court had jurisdiction to certify. This case did not stop there. One of the principal grounds of defence was anticipation of patent by Mr. A. P. Trotter, an electrician of great eminence, who was now electrical adviser at the Cape. His evidence had been taken on commission, and did not support the defendants' contention, now abandoned, that his own patent anticipated the Holophane; he said it was outside the Holophane patent altogether. Considerable expense had been entailed in going out to the Cape, and they might take it that the defendants had come to the conclusion that they could not resist the action. So that really there was no reason for withholding the certificate which his lordship would have given if he had put one witness in the box, and counsel for the other side had said that he could not carry the case further. There was only one case he could find, a judgment by Mr. Justice Kay, which went against his contention that the plaintiffs were entitled to a certificate that the validity of the patent had come into question, and that was on the ground that there was no appearance. There was a mass of evidence taken on commission on the file which supported the plaintiffs' case. Sometimes a certificate had been refused where there was a possibility of collusion, but there was no suspicion of the kind in that case. It had been fought out to the very last moment, and was defended both on the action and on the original motion.

Mr. CANN, for defendants, said he submitted to the order. They had come to an arrangement with plaintiffs, and there was an honourable understanding that defendants abide by his lordship's decision upon this point of certifying.

Mr. Justice KEKEWICH said an injunction would issue on the terms agreed upon. As to the certificates which he was asked to grant, he said without hesitation that the tendency of the Courts had been to refuse a certificate unless the Court was first satisfied, as it could only be by hearing witnesses and examining documents, that the certificate ought to be granted. He was asked to certify that the plaintiffs' certificates of breaches were reasonable and proper without understanding them, without knowing how far they could be proved or might fail. That was not a proper exercise of judicial functions. As regards the second certificate for which he was asked, that the validity of the plaintiffs' patents had come into question, he asked himself why that certificate was wanted. It would not increase the costs payable to the plaintiffs now, but it would enable them on another action if they won—as they might win—without doing more than filing a statement of claim against a defendant who did not appear, to tax costs as between solicitor and client. That was a very great advantage to a patentee, and plaintiffs sought to obtain it in a case in which, so far as his lordship knew, if it were fought out the letters patent might prove to be invalid. His lordship did not think that in a case where invalidity had been pleaded and at the last moment the defendants submitted, he ought to grant a certificate. While agreeing with the statement that there was no collusion here, such a course might open a door to possible oppression of other defendants. On those grounds the certificates must be refused.

Judgment accordingly.

Earl of Galloway v. Elieson Lamina Accumulator Co. (Limited).

This action came before Mr. Justice Kekewich, on Saturday, on a motion for judgment on default of appearance in a debenture-holder's action, and Mr. Justice KEKEWICH (addressing counsel for plaintiffs) said, although counsel did not ask to continue the manager after Jan. 31, 1899, he should extend the time if possible.

Mr. WARRINGTON, Q.C. (for plaintiffs) said that they hoped to sell the undertaking as rapidly as possible, and if his lordship would continue the manager until some time after the sale he should be glad.

His LORDSHIP: I think you had better say till April 30.

Mr. WARRINGTON said that there ought to be an inquiry as to the debentures.

Mr. Justice KEKEWICH: Not only that, but I think there ought to be an inquiry as to the other charges. I have generally found it necessary, and it does not add to the expense.

Mr. WARRINGTON: It is proposed to sell at the present moment the business, stock-in-trade, book debts and other assets, with liberty to apply in chambers as to the other property. Sale was the only way to protect the assets.

Mr. Justice KEKEWICH said he did not care to order a sale, as a rule. The plaintiffs were entitled to a charge, but it was a charge which could not be effective.

Mr. WARRINGTON: No; your Lordship sees that at the time the money comes into Court the debentures will become due. They will become due on non-payment of interest. Interest is payable half-yearly on June 30th and December 30th, so that it will become due on December 30th, and the principal money will become due three months after default. It will become only a question of the plaintiffs receiving their debentures out of the proceeds of the sale. If something is not done the assets will all disappear. It is desirable to sell the business at once as a going concern, and to sell the stock-in-trade at once as it is likely to injure if kept for any length of time. Your lordship can order the stock-in-trade to be sold at once, but it would be a serious loss to everybody to sell the stock-in-trade by itself. That would be breaking up everything. I submit there being a charge your lordship has the means of protecting the property. The debenture holders are entitled to a charge in virtue of the debentures, and your lordship is entitled to make an order for sale although it may be that they cannot be paid immediately out of the proceeds of the sale.

Mr. Justice KEKEWICH: I think I may go that far. This is goodwill and stock-in-trade. You only ask me to sell the business. The minutes must, therefore, be altered.

Pearson v. Hartnell.

At the Leeds County Court, on Wednesday, this adjourned action, which was for the recovery of £280. 12s. compensation for injuries received while in the employment of Mr. Wilson Hartnell, of Leeds, was heard. Full particulars in this action were given in our issue of the 28th ult. After hearing further evidence, judgment was given for the defendant, but without costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury court, Fleet-street, London:—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

Digitized by Google

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 8d. each, post free.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

IN THE PRESS.

"THE ELECTRIC ABC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY." By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R. Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

Extension of Time.—The *Salford* Electric Lighting committee invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walness-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, *by Dec. 15, not Dec. 1, as originally advertised.*

The *Beckenham* District Council invite tenders for the supply of the following electric lighting plant:—(*a*) Water-tube boilers and economiser; (*b*) steam alternators, transformers and switchboard; (*c*) pipework, feed pumps, overhead tank, feed-water heater, &c.; (*d*) arc lamps, lamp posts, &c.; (*e*) cables and street work; and (*f*) travelling crane. Specifications, &c., can be obtained after the 21st inst. from the consulting engineers (Messrs. Wilson and Story), 66, Victoria-street, London, S.W. Further particulars are set out in an advertisement elsewhere, and tenders must be sent to the clerk to the council (Mr. F. Stevens) by noon of Saturday, Dec. 17.

The *Shoreditch* (London) Vestry invite tenders for the supply of six direct-current rotary transformers, with switch gear complete, three of 66 kilowatt and three of 33 kilowatt capacity. Further particulars are given in an advertisement elsewhere. Tenders must be sent in not later than noon of Tuesday, Dec. 13, to the chief electrical engineer (Mr. C. Newton Russell), Electricity Supply Department, Coronet-street, Shoreditch.

The Corporation of *Barnsley* invite tenders for the supply and erection of: (1) Lancashire boilers and Green's economiser; (2) engines, dynamos, switchboard, condensers, feed-water pumps, balancing transformers, boosters, piping, tanks, crane, wiring of works, and engine, &c., foundations; (3) secondary batteries and accessories; (4) feeder and distributing mains (solid system); (5) potential leads, network and service boxes and service connections. Further particulars in our advertisement columns, and specifications, &c., can be obtained on application to the consulting engineer (Mr. Thos. L. Miller), 7, Tower-buildings, N., Water-street, Liverpool. The Corporation also invite tenders for the erection of a chimney and engine, dynamo and boiler house, storage rooms and offices. Specification, &c., from Mr. J. Henry Taylor, borough surveyor, to whom tenders should be sent by noon of Monday, Dec. 12th.

The *North-Eastern Railway Co.* invite tenders for the supply of telegraph apparatus, wire and line stores during the six months ending June 30, 1899. Some further particulars are set out in an advertisement elsewhere. Forms of tender from Mr. Graves, telegraph department, York, and tenders must be sent to the secretary (Mr. C. N. Wilkinson), at York, by noon of Monday, Dec. 5.

The *Shanghai* Council also invite tenders for a concession, for a period of 30 years, for the exclusive right of establishing and working a telephone system in Shanghai. Further particulars are set out in an advertisement on another page, and plans may be seen and particulars obtained on application to Messrs. John Pook and Co., 8, Jeffrey's-square, St. Mary Axe, London, E.C. Further information may be obtained on application to Mr. Charles Mayne, municipal engineer, Shanghai, whose telegraphic address is "Dynamo Shanghai." Tenders must be sent to the secretary (Mr. J. O. P. Bland), Shanghai, by noon of Friday, March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, secretary, by noon of Wednesday, March 15, 1899.

Tenders are invited by the *Board of Control, Dublin*, for the supply of the necessary plant, wiring, &c., for the electric lighting of Richmond District Lunatic Asylum. Tenders to Mr. H. Williams, Custom House, Dublin, by 10 a.m. Dec. 5.

The *Great Northern Railway Co.* invite tenders for the supply of new, and the purchase of old, stores for 12 months from Jan. 1. Patterns will be exhibited at the Stores Department, Doncaster, where they may be inspected up to 5th prox. Tenders, addressed to the Stores Committee, must be sent to the Company's offices at King's Cross, London, N., by 10 a.m. on Tuesday, Dec. 6.

The *Glasgow* Corporation invite tenders for supplying switchboards and instruments at the new electricity works, Port Dundas. Tenders to town clerk (Sir J. D. Marwick) by Dec. 5.

The *Dublin* United Tramways Co. invite tenders for the supply of general stores, including electrical supplies, car fittings, ironmongery, &c., for the year 1899. Tenders to the chairman of the Company, 9, Upper Sackville-street, Dublin, by 5th prox.

The Electric Lighting committee of the borough of *Middlesbro'* require tenders for the supply and erection of electric generating plant, &c. Tenders to Mr. Geo. Bainbridge, Municipal Buildings, Middlesbro', by Nov. 29.

The *Halifax* Corporation require tenders for meters, house and sub-station transformers, arc lamp transformers and alternating current arc lamps. Particulars from borough electrical engineer.

The *Shoreditch* (London) Vestry invite tenders for boring an artesian well at the electricity works. Tenders to Vestry Clerk, Town Hall, Old-street, E.C., by Dec. 12.

The *Coventry* Electric Light committee require tenders for the erection of five electric sub-stations. Tenders to the town clerk by Dec. 13.

The *Tanfield* District Council invite tenders for electric lighting plant. Particulars from Mr. R. Heslop, Burnopfield, R.S.O., to whom tenders by 29th inst.

The *French* Post and Telegraph Authorities require tenders for supplying 80 kilometres of submarine cable core, 30 tons of galvanised iron wire (5mm. dia.), and 100 tons of galvanised iron wire (8mm. dia.). Tenders to Sous-Secretariat d'Etat des Postes et des Telegraphes, 103, Rue de Grenelle, Paris, by Dec. 6.

TENDERS RECEIVED AND ACCEPTED.

The *Watford* District Council have accepted the tender of the Reason Manufacturing Co. for supply of cut-outs, and that of Messrs. Venner and Co. for the supply of Hookham electricity meters to their electricity department.

The *Wimbledon* District Council have accepted the tender of the British Electric Transformer Manufacturing Co. for the supply of transformers and boxes at £1,960. 13s. 6d.

The *Barnsley* Town Council have accepted the tender of Mr. J. Taylor to provide electrical communication between the central fire station and the houses of firemen, for £102. 10s.

The Electric Lighting committee of the *Edinburgh* Town Council recommend the acceptance of the tender of Messrs. Mather and Platt for the supply of steam engines and dynamos for the new electricity supply station in M'Donald-road. The amount of the contract is about £40,000. Two of the new machines must be delivered by Aug. 15, two by Sept. 15 of next year, and the remaining two on a later date. In all there will be 17 boilers to contract for, amounting to about £20,000; Mr. Sinclair has

Digitized by Google

obtained the contract for seven, and Messrs. D. Stewart and Co. for six, to be delivered on Aug. 15 and Sept. 15. The remaining four boilers, two from each contractor, are to be delivered at a later date. Altogether there will be installed next year at M'Donald-road station more machinery than there is at Dewar Place at the present time, and the committee will be able to supply current to more than double the present number of lamps.

The *Hornsey* District Council have accepted the tender of Messrs. Jukes, Coulson, Stokes and Co. for the supply of cast-iron telephone pipes. The following tenders were received :—

	Pipes.	Covers.
Jukes, Coulson, Stokes & Co. (*accepted*)	£6 5 0	£1 3 9
Gibb and Co.	6 3 4	1 7 0
Newton, Chambers and Co.	6 5 0	1 17 6
Bird and Co.	6 5 0	1 6 4
Hollom and Co.	6 10 0	1 7 0
Stanton Iron Co.	6 18 6	1 17 6
Pontifex and Co.	7 0 0	1 10 0
H. and G. Measures	12 0 0	1 3 0

The Tramways committee of the *Liverpool* City Council have accepted the tender of the Leeds Steel Works, for the supply of steel rails, for the new Aigburth-road extension, at £7 per ton.

APPOINTMENTS VACANT AND FILLED.

A technical instructor is required for the Thomason Engineering College, Roorkee, India. Further particulars are given in our advertisement columns, and applications must be sent in, on forms to be obtained from the Director-General of Stores, India Office, Whitehall, London, S.W., not later than 28th inst.

The Electricity committee of the borough of Ashton-under-Lyne require an assistant engineer. Salary £130 per annum. The committee also require a switchboard attendant for a three-wire and traction switchboard. Particulars in our advertisement columns. Applications, addressed to chairman of committee, must be in by Dec. 7.

The Wimbledon District Council require a resident electrical engineer. Salary £250 per annum. An advertisement elsewhere contains further particulars. Applications must be sent to the clerk (Mr. W. H. Whitfield), Council Offices, Broadway, Wimbledon, by 10 a.m. of Tuesday, Dec. 6.

The Vestry of St. Mary, Newington, London, require a resident electrical engineer to take charge (under the superintendence of the consulting engineers) of the erection of the machinery at their electricity generating station. Salary £250 per annum. Applications to Mr. L. J. Dunham, Vestry Hall, Walworth-road, S.E., by Dec. 2.

As announced in our advertisement columns the Leyton District Council require a book-keeper, who understands electric lighting accounts. Commencing salary £100, rising to £150 per annum. Applications to the chief electrical engineer (Mr. H. Collings Bishop), Cathall-road, Leytonstone, by Dec. 3.

The Leith Town Council require for their electric lighting department two assistant engineers, jointer, arc lamp trimmers, mains superintendent, switchboard hands, clerks, &c. Applications to convener of Electric Lighting committee by Nov. 26.

Mr. John Young, the tramway manager at Glasgow, has been chosen by the General Purposes committee of the London County Council as superintendent of the London tramways. The salary attached to the office is £1,500 per annum.

Mr. Theodore Parsons, of Bath, has been appointed assistant electrical engineer at the Halifax Corporation electricity works.

Mr. S. L. Smith, London, has been appointed third assistant engineer at Southampton.

At the meeting of the Worcester City Council, on Tuesday, Mr. C. J. Sutherland, of Hanley, was appointed city electrical engineer at a salary of £350 per annum. Mr. Sutherland has for some years occupied the post of joint electrical engineer and manager (with Mr. C. A. Cowell) of the Hanley electricity works.

BUSINESS NOTICES.

The Notting Hill Electric Lighting Co. (Limited) have removed to new offices at 140, High-street, Notting Hill Gate, London, W., adjoining the works.

Attention is called to a legal notice which appears in our advertisement columns relating to the action decided on Tuesday by Mr. Justice Kekewich in the Chancery Division, dealing with the manufacture and sale of Holophane globes and shades.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting will be held at Swan House, Great Swan-lane, London, E.C., on Dec. 21, to receive an account of the winding up of the Times Electric Lamp Co. (Limited).

At a meeting of the United Ordnance and Engineering Co., on 14th inst., it was decided to wind up the company *voluntarily*, and Mr. W. E. Davies, of Broad Sanctuary-chambers, Westminster, was appointed liquidator.

Creditors of J. Goodman and Co. (Limited) must send particulars of their claims to the liquidator, Mr. J. F. Lovering, 3, Church-passage, Guildhall, London, E.C., by Dec. 29.

Creditors of Rose and Bird (Limited) must send particulars of their claims to the liquidator, Mr. A. H. Rose, 24, Stamford-street, by Dec. 9. It will be remembered that this company recently went into voluntary liquidation for the purpose of amalgamating with the Crystal Electric Lamp Co.

Plant for Sale.—The Glasgow Corporation invite offers for the purchase of two 200 H.P. boilers, two 200 H.P. engines and four 50-light Brush arc light dynamos. Further particulars from the city electrical engineer (Mr. W. A. Chamen), 75, Waterloo-street, and tenders to the town clerk (Sir J. D. Marwick), City-chambers, Glasgow, by Dec. 6. See also advertisement.

Storage Batteries.—The following letter has appeared from Mr. Marshal Halstead, United States Consul, 16A, Corporation-street, Birmingham :—

Perhaps in your desire to be useful to Birmingham manufacturers you may wish to give circulation to the following inquiry, which I have received from a firm of merchants in the United States :—"We are looking for a chloride storage battery, to run about 150 hours without being recharged. If you know of any one in your territory who makes such a battery please put us in commuication with them. We want a price on 1,000 to 5,000 of these, delivered in London. Any information you can give us in relation to this matter, or the whereabouts of storage battery people, will be appreciated." If British manufacturers of storage batteries wish to get into correspondence with the American merchants making the inquiry they may address their communications to me (open), and I will forward them with due promptness.

Collision.—On Thursday the new cable steamer "Anglia," of the Telegraph Construction and Maintenance Co's. fleet, while at anchor in the Thames taking in cable and stores, was run into by another vessel and received damage which will necessitate her being put into dock for repairs.

Trades Unionism and the Wages Question.—We have received from Mr. F. E. Sims, general secretary of the Electrical Trades Union, copies of correspondence that has passed between the Union and Her Majesty's Office of Works with reference to the discharge of a member of the Union from his employment as an electrical wireman. The correspondence extends from June 9 to Nov. 11, and commences with a request, from the workman, for an increase of wages on the ground "that the rate of pay was below the minimum rate paid by contractors." In this letter it is stated that a large number of electrical contracting firms pay 9½d. and 10d. per hour to wiremen, and 11d. and 1s. per hour to charge hands. This application was met by a refusal, on the ground that the wages paid were fair for the class of work being done by the applicant. This was shortly afterwards followed by the dismissal of the aggrieved workman, on the ground that his services were no longer required. Subsequent letters between the parties concerned and the First Commissioner of Works complete the correspondence. We have only room for the following, which expresses the views of the Union and the reply of the Department :—

"To the Right. Hon. A. Akers-Douglas, M.P. "September 16, 1898.

"SIR: I am requested by my committee to bring before your notice the action of your engineer at the Houses of Parliament Electrical Department in dismissing one of our members, who was employed as an electrical wireman at St. Stephen's House, S.W. He was discharged on July 2 last on the ground that the Department had no further need for his services. We contend that he has been discharged because he ventured to ask for a higher rate of pay than the Department are at present paying, and for no other reason. At the time he was discharged, other men were taken on and kept on for weeks, so that slackness cannot be urged as the reason, and we are in a position to prove that Mr. Fennimore, foreman of the Department, told other men in the Department's employ, that the reason he was discharging Mr. Calipe was because he was dissatisfied, as he had asked for 9½d. per hour and they were only paying 9d. No fault was found or could be found with his work, and we contend that the Department treated this man very unfairly in discharging him because he ventured to ask for ½d. an hour rise. The reason that this man wrote in for a higher rate of wages than the Department was paying was because, to begin with, the men in the employ of the Department are allowed only to work 50 hours a week, which, at 9d. per hour, amounts to £1. 17s. 6d. When we are working for electrical firms we work at least 53 or 54 hours, so that the men lose at least 2s. 3d. per week, as compared with that they get in outside firms. As there are several firms who pay 9½d. per hour, the discharged man thought that there would be no harm in calling the Department's attention to it, and suggesting that considering the loss involved the Department might see their way to increase his wages by ½d. per hour. There was no suggestion that he would leave or was dissatisfied; the advance was simply asked as a matter of justice, with the result that he was discharged for so doing.—F. E. SIMS, Gen. Sec."

[REPLY.] "October 14, 1898.

"SIR: With reference to your letter of the 16th ultimo relative to the discharge of an electrical wireman in the employment of this Department, I am directed by the First Commissioner of Her Majesty's Works, &c., to

Digitized by Google

acquaint you, for the information of the Electrical Trades Union, that the man in question was dismissed because he was an unsatisfactory workman, and his discharge was in no way connected with his request for an advance of wages.—REGINALD BRETT."

Telephones and Telephone Accessories.—We have received from Messrs. W. F. Dennis and Co., 23, Billiter-street, London, E.C., a general price list of telephones, switchboards, and telephone instruments and accessories, manufactured by the Antwerp Telephone and Electrical Works, for which firm Messrs. Dennis and Co. are sole agents in this country.

Wires Price List.—Messrs. Ward and Goldstone, of Manchester, forward a price list of insulated high-conductivity wires.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Nov. 16 to Nov. 22, with the ports of destination :—

Aden—£895 (telegraph material). *Argentina*—Buenos Ayres, £804. *Australasia*—Adelaide, £73 ; Launceston, £90 ; Melbourne, £476 ; Rockhampton, £313 ; Sydney, £1,023 ; Wellington, £32. *Belgium*—Brussels, £30 ; Ostend, £10. *Brazil*—Bahia, £217 ; Rio Janeiro, £32. *Canada*—Halifax, £18 ; Quebec, £100. *Ceylon*—Colombo, £81. *China*—Shanghai, £1,180 (incl. £1,087 telegraph material) ; Tientsin, £79 (telegraph material). *Denmark*—Copenhagen, £84. *Germany*—Hamburg, £110. *Holland*—Amsterdam, £61; Rotterdam, £107 (telegraph material). *Hong Kong*—£122. *India*—Bombay, £140 ; Calcutta, £829 (including £329 telegraph wires ; Madras, £38. *Japan*—Yokohama, £644. *Malta*—£157. *Mexico*—Vera Cruz, £33 (telegraph material). *Norway*—Christiana, £460. *Russia*—Helsingfors, £43. *South Africa*—Cape Town, £54 ; Durban, £2,246 ; East London, £151 ; Port Elizabeth, £73. *Spain*—Malaga, £40 telegraph cable). *Straits Settlements*—Penang, £118 (telegraph material) ; Singapore, £58. *Sweden*—Gothenburg, £103 ; Stockholm, £189 (telegraph material). *United States*—Boston, £45. *West Africa*—Senegal, &c., 55 knots telegraph cable. Total, £11,358 against £22,140 in the corresponding week last year (Nov. 17 to 23).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Aberdeen.—A bill is being promoted by the Corporation for the extension of the tramways and for the introduction of electric traction. A deputation has been appointed for the purpose of visiting the Glasgow electric tramways in order to obtain information for the guidance of the Council. The visit of the deputation, which will be accompanied by the burgh surveyor and the electrical engineer (Mr. J. A. Bell), will take place on Dec. 6.

Aberystwith.—The District Council have entered into a new agreement with the Aberystwith Electric Lighting Co. for the public lighting. The annual charge for current to, and maintenance of, each arc lamp is now £17. 17s. against £20 previously.

Alleged Perjury.—John Limbrey Higgs, Delahay-street, again appeared before Mr. Lushington, at Bow-street Police Court, to an adjourned summons charging him with having committed perjury in the course of his examination in connection with the winding up of the I.E.S. Accumulator Co. (Limited). Over two hours were occupied in the cross-examination of the mortgagor, Mr. John Walton, but eventually the case was again adjourned till 29th inst.

Argentine.—A law passed on Sept. 22 by the Argentine Congress (which remains in force until Dec. 31) increases certain of the Customs duties. *Ad valorem* duties of 5 per cent. and under are doubled, above 5 per cent. are subject to 10 per cent. additional, and 10 per cent. on Customs law. Among the goods which come under the 5 per cent. *ad val.* classification are electric light and power plant and apparatus (except meters and fittings) and steam motors.

Ayr.—The Town Council, which has had under consideration a lengthy report from Mr. I. E. Winslow, on the construction of electric tramways, have decided to obtain a provisional order for an electric tramway from Burns's monument to Prestwick Cross. A scheme for the construction of a light (electric) railway in the district is to be opposed.

The salary of the burgh electrical engineer (Mr. A. J. Fuller) has been increased from £250 to £300 per annum. The Lighting committee recommend the Police Commissioners to obtain parliamentary powers for wiring buildings in that town on the easy payment system.

Battersea (London).—The Vestry have appointed Mr. H. Riley, 28, Victoria-street, S.W., to get out quantities in connection with the projected electric lighting station.

Birmingham.—At a meeting of the City Council, on Wednesday, proposals regarding the purchase of the undertaking of the Birmingham Electric Supply Co. at £420,000 were approved, and the draft bill of the Council was passed. Powers to borrow £500,000 are being sought

Brighton.—The Town Council have decided to create a special Tramways committee to deal with the proposal to construct electric tramways in the town.

British Columbia.—One of the most important improvements in Victoria, B.C., during 1898 has been the extension of the lines of the Western Union Telegraph Co. to the city. This line has been in operation since June 9. The Western Union Co., being incorporated under the laws of the United States, has no right to operate in Canada, and consequently the line connecting with Port Angeles, Washington, is operated by the Great North-Western Telegraph Co., connecting with the Western Union Co.'s service. The new line has a cable across Puget Sound, from Seattle to Port Townsend, thence by land to Port Angeles, thence a cable across the straits of Juan de Fuca to Albert Head, and thence by land to Victoria. Since this line was built the Canadian Pacific Railway Co. has laid a cable from Victoria to Port Angeles direct, so that now Victoria has two telegraph lines direct to the States. Each company works duplex. During August the work of conducting power from the Sooke Mountains, 18 miles distant from the city, for the electric tramroad and the illumination of Victoria by electricity, has been completed. The water from the mountains starts 2,300ft. above the level of the sea, and is the highest fall in Canada. About 700ft. above sea level and 16 miles from Victoria, these waters form a lake covering 150 acres, into which empties Goldstream River, which is tapped 3 miles from its source by an artificial lake or reservoir covering 7½ acres, 1,122ft. above sea level. From this reservoir the water passes through a steel pipe 33in. in diameter, 6,700ft. to the power house, which is 460ft. above sea level, thus giving a fall of 1,000ft. from the main lake, and through this pipe 15,000,000ft. of water pass every 24 hours, giving 1,500 H.P. In the power house, located at the foot of a mountain, is an electric plant which is said to be without a rival for size and completeness on the North Pacific coast. This plant was supplied by Messrs. Hasson and Hunt, of San Francisco. From the power house current is carried 12 miles to the city, and furnishes power sufficient to operate the street-car and electric light systems and private supply to a number of offices and factories.

Burnley.—A Local Government Board inquiry was held here last week into the application of the Town Council to borrow £10,000 for further extensions of the electric lighting system. £25,000 is already being spent on extensions, and the additional loan is required for new mains to meet the rapidly increasing demand for current.

Camberwell (London).—The Vestry has decided to wire the Vestry Hall and offices for the electric light.

City of London.—At the meeting of the Common Council last week the Streets committee presented a report on the application of the Metropolitan Electric Supply Co. for the Corporation's consent to an application for a provisional order for the supply of electricity within the City. The committee recommended that the company should be informed that the Corporation regretted it was unable to give its consent to the application. The report was adopted.

Cork.—The first experiment in electric street lighting was made on the 15th inst., when current was switched on to the arc lamps erected in Patrick and Bridge-streets.

Croydon.—A Local Government Board inquiry was held here last week into the application of the Town Council to borrow £2,250 for the purchase of that portion of the undertaking of the Crystal Palace District Electric Supply Co. within the borough of Croydon, and £850 for erecting a sub-station at Upper Norwood.

Darwen.—A town's meeting on Wednesday approved the proposals of the Town Council to acquire the local tramways, to construct additional lines, to introduce electric traction, and to carry out other improvements at an estimated cost of £150,000.

Dublin.—The report of the Electric Lighting committee presented at the meeting of the Corporation on Monday stated that the gross income for the year 1897 had been £13,089, expenditure £8,036. After allowing for interest and sinking fund there was a credit balance of £953. Ald. Meade stated that application would be made for sanction to borrow a further £8,000 for the renewal of the mains. Pending this loan the committee had confined their efforts to putting the existing mains into fair order. The report was adopted.

Edinburgh.—Since Oct. 17 applications for an equivalent of 7,252 8 c.p. lamps have been received. In another column some particulars are given of the tenders accepted for the supply of plant for the new station at M'Donald-road.

Electric Lamps in Japan.—Writing on Sept. 1 last, on the subject of the outlook for the electric lamp trade in Japan, the United States Consul at Yokohama says :—"Almost every prominent American and European manufacturer of these goods is represented here either by specially-appointed agents or by correspondents. The Edison-Swan Company (British), Siemens and Halske, Severin Senator, and the General Electric Co. (Berlin) may be mentioned as leading European concerns here, who, by their agents, are making strong efforts to secure a large

Digitized by Google

share of the trade. German 16-c.p. lamps, guaranteed for 1,000 hours, have been offered here for 6d. each. American and other lamps of the same quality are now selling here for 8d. each. This unusually low price is the result of over competition, and will probably be of short duration."

Electric Lighting Notices.—Notice of intention to apply for provisional electric lighting orders has been given by the following:

Corporations of Durham, Heywood, Kilmarnock, Mansfield and Rawtenstall.

District Councils of Ashford, Audenshaw, Bognor, Cheriton, East Barnet, Failsworth, Fenton, Halesowen, Pemberton, Stourbridge, Swinton, Wath-upon-Dearne, and Worksop, and the Township Commissioners of Clontarf (Dublin).

County of London and Brush Provincial Co. for Bermondsey, Rotherhithe, Deptford, Lambeth, Lewisham, and Lee (London); Charing Cross and Strand Electricity Supply Corporation and Metropolitan Electric Supply Co. for City of London; Smithfield Markets Electric Supply Co. for City of London, St. Luke's and Holborn; West Kent Electricity Supply Co. for Bexley, Crayford and Erith; Camborne Electricity Supply Co. for Camborne; Blackheath and Greenwich District Electric Light Co. for Lee; Drake and Gorham Electric Light (Pioneer) Syndicate for Musselburgh; Ventnor Electric Light and Power Co. for Newport (Isle of Wight); Kelvinside Electricity Supply Co. for Partick; Ryde Electric Light and Power Co. for Ryde; Laing, Wharton and Down for Slough and Datchet; Weston-super-Mare and District Electric Light and Power Syndicate for Weston-super-Mare; and Mardy Electric Lighting Co. for Ystradyfodwg (Glam.).

In the following cases notice to proceed by private Bill has been given:—

Corporations: Birmingham, for powers to purchase the undertaking of the Birmingham Electric Supply Co., and to extend the company's area of supply; Loughborough, to supply electric current, to sell and let on hire electric motors, &c.; Manchester, for lighting culs de sac, to purchase and let on hire electric motors and other electrical apparatus, to establish an insurance fund, for borrowing powers, &c.; Whitehaven, to extend electric lighting area.

Companies: Kensington and Knightsbridge Electric Lighting Company, and the Notting Hill Electric Lighting Company, to acquire lands and erect a generating station in the parish of Hammersmith (London), and to lay mains therefrom into the areas of supply of both companies; St. James's and Pall Mall Electric Lighting Co. to purchase compulsorily land in the parish of St. James's, Westminster, and to erect generating station thereon and for other powers; Central Electric Supply Co. to generate and supply electric energy "in bulk," and to erect generating station in the parish of St. Marylebone; County of London and Brush Provincial Electric Lighting Co. to compulsorily acquire certain lands and buildings in the parishes of St. James (Camberwell), Wandsworth, St. Luke's (Middlesex) and St. James (Southwark), and other parishes; Walker and Wallsend Union Gas Co. to generate and supply electric current.

Bills will also be presented:

To incorporate a company to be called the South Lancashire and Cheshire Electricity Co., to generate and supply electric current within parts of the counties of Lancaster and Chester (including St. Helens, Widnes, Warrington, Wigan, Liverpool, Runcorn, Eccles, and Bolton), to enter into agreements with local authorities and others; to incorporate a company to be entitled the Leicestershire and Warwickshire Electric Supply Co., to generate and supply electrical energy within parts of the counties of Leicester, Warwick, and Derby (including Birmingham, Leicester, Coventry, Sutton Coldfield, Rugby, Leamington, Warwick, Ashby, Market Bosworth, Tamworth, Atherstone, Hinckley, Coleshill, Lutterworth, Nuneaton, Burton, Lichfield, and Derby), and to enter into agreements with local authorities and others; to incorporate a company to be entitled the Lancashire Electric Power Co., to generate and supply electricity within parts of the counties of Lancaster and Chester (including Liverpool, Manchester, Preston, Burnley, Bolton, Blackburn, Oldham, Widnes, St. Helen's, Stockport, Macclesfield, Birkenhead, Salford, Accrington and Darwen); to incorporate a company to acquire undertakings of Crowborough District Gas and Mayfield District Gas Light Companies, and to enable the company to generate and supply electric current for lighting and other purposes.

Electric Power Schemes for Lancashire.—As will be seen from the list of official notices given above, bills are being promoted to incorporate companies to generate and sell electric current for public and private lighting, motive power, heating, chemical reduction, trade manufacturing, and all public and private purposes in Lancashire and Cheshire. The proposed area of supply includes St. Helens, Widnes, Warrington, Wigan, Prescot, Leigh, Hindley, Ormskirk, Liverpool, Birkenhead, Runcorn, Eccles, Manchester, Bolton, Horwich, Chorley, &c., besides all other boroughs, towns, &c., within the district. Powers are also sought to acquire, construct, maintain and use, and to sell, let and otherwise dispose of machinery, plant and apparatus connected with electric supply, &c. One of these companies is to have an authorised capital of £1,000,000.

Electric Traction Notices.—Official notice of intention to apply for provisional tramway orders, to be worked electrically, has been given by the following:—

The Corporations of Belfast, Blackpool, Hastings, Reading and Southport, and the District Councils of Audenshaw, Barking, Matlock and Moss Side; the Gravesend, Rosherville and Northfleet Tramways Co., to construct additional tramways, introduce electric traction, and to sell the undertaking to the Drake and Gorham Electric Power and Traction Co.; and the Ipswich Tramways Co. to construct additional tramways, to use electric traction, and to sell undertaking to the Drake and Gorham Electric Power and Traction Co.

In the following cases procedure, by private bill, has been decided upon:—

Corporations: Blackpool, Bradford, Halifax, Leeds, Sunderland, Bury, Darwen, Derby, Gt. Yarmouth, Oldham, Wolverhampton, Manchester, Stockport, Newcastle-on-Tyne and Nottingham.

Companies: Baker-street and Waterloo Railway Co., British Electric Traction Co. (for Bexhill and St. Leonards, Hastings), Brompton and Piccadilly Circus Railway Co. (to enter into agreement with Metropolitan Railway Co. to guarantee interest, &c.), Charing Cross, Euston and Hampstead Railway Co., Central London Railway Co., City and Brixton Railway Co., London United Tramways, and the South Staffordshire Tramways Co.

Bills will also be introduced:—

To incorporate a company to construct an underground (electric) railway from Wood Green to the Fleet-street end of the Strand (London), and to incorporate a company, to be entitled the North West London Railway Co. to construct an underground (electric) railway from the Marble Arch to Cricklewood.

Exhibition Lighting.—One of the features of the Jubilee Cattle Show, which was opened on Saturday, at Bingley Hall, Birmingham, is the installation of a permanent electric lighting plant by the Walsall Electrical Co. Hitherto the electric lighting has been of a temporary character.

Fire.—A serious fire occurred on Friday at the works of Messrs. Hick, Hargreaves and Co., engineers, of Bolton. The damage was very great, and 300 employés are affected.

Gainsborough.—The District Council are promoting a bill for the acquisition of the gas company's undertaking and for power to generate and supply electric current.

Glasgow.—At a recent meeting of the Electricity committee it was reported that the Kelvinside Electricity Co. were willing to dispose of their undertaking to the Corporation for £50,000. The committee are willing to pay £30,000, being the amount of the company's outlay in establishing the business, and what they consider is the value of the goodwill. The Corporation and the Partick Commissioners will oppose the company's application to extend their powers to Partick.

The question of equipping the Govanhill tramway route on the overhead trolley system has been postponed pending the presentation of an analysis by the general manager (Mr. Young) of the report recently received from the Metropolitan Street Railway Co., of New York, in which three months' experience of the working of the conduit system on that line was dealt with. Reference to this report will be found in our last issue.

Great Grimsby.—The Public Lighting committee have approved the plans of the proposed electricity supply works.

Greenock.—The burgh electrical engineer (Mr. S. E. Fedden, late of Edinburgh) has taken up his duties.

Hants.—The County Offices at Winchester are to be wired for electric light. Current will be taken from the mains of the Winchester Electric Light and Power Co.

Heckmondwike.—Mr. W. C. C. Hawtayne has been appointed consulting engineer to the District Council, in connection with their proposed electric lighting scheme.

Imperial Penny Post.—Ceylon has arranged to join the Imperial Penny Postage movement, and letters between the United Kingdom and Ceylon can be sent after Christmas day at the cost of a penny each.

Institution of Engineers of the River Plate.—There has recently been established at Buenos Ayres an institution which embraces members of all branches of the engineering profession. It was originally intended to establish an electrical engineering institute, but, upon discussion amongst probable members, the larger scheme was adopted, and on Sept. 29 the following gentlemen were elected members of the governing council:—

President: J. W. McCrosky.
First Vice-President and Secretary: Ernesto Danvers.
Second Vice-President: T. L. Chubb.
Third Vice-President: Malcolm Graham.
Treasurer: L. B. Trant.
Committee: J. Abella, W. B. Basset-Smith, C. Cicogna, E. W. Dean, Percy Grant, G. H. Green, J. Marjoribanks, H. Randolph, J. R. Sutton and E. Wilson Woods.

The movement to establish the institution has been very successful, over 60 members having joined up to the 10th ult. The memorandum and articles of association have been approved, and the new society, which owes its initiation mainly to its first vice-president and secretary (Mr. Ernesto Danvers), has started upon what promises to prove a successful career. The new institution will doubtless form a rallying point for the large number of engineers of all nations whose work lies in the Plate region.

Islington (London).—In moving the adoption of a report of the Electric Lighting committee recommending the execution of certain

Digitized by Google

building work at the electricity station, Mr. Gordon announced that, if the work were not completed within six months, they would have to disappoint a large number of customers who had applied for current. Eventually the recommendation was referred back in order that the work may be put up for public tender.

Japan Customs Tariff.—The rates of import duties established by the recent general tariff law of Japan places a duty of 10 per cent. *ad valorem* upon electric light machinery and parts thereof, telephones and telephone parts, telegraph wire (galvanised, tramway cars and carriages and parts thereof, submarine cables and subterranean telegraph wires; and 20 per cent. *ad valorem* on lamps, lanterns and parts thereof. Articles which enter Japan duty free include printed books and pamphlets, and scientific diagrams.

Klondyke.—The Dominion Government have granted a charter to the Northern Commercial Telegraph Co. for the construction of a telegraph line from the head of the Lynn Canal, or Skagway, to Dawson City, *vid* Lake Bennett and Selkirk. The company also has the sole right to lay a cable from Vancouver to Skagway. It will probably be some time before the cable is laid, but the overland wire is to be in operation by April or May at latest.

Lewisham (London).—The Crystal Palace District Electric Supply Co. recently obtained sanction of the London County Council to lay mains in a portion of the district controlled by the Lewisham District Board of Works. As this permission had been given without prior sanction of the local Board of Works this body, except upon onerous conditions, refused its consent. The company appealed to the Board of Trade, but the appeal was disallowed. Several similar cases to the above have recently occurred, notably at Bermondsey, where the Vestry has strongly protested against the action of the L.C.C. in granting certain facilities to the London Electric Supply Corporation without first taking the opinion of the Vestry on the subject.

Limerick.—The Board of Trade have notified the Town Council that the revocation of the Limerick provisional order will shortly be considered. The order was obtained in 1892.

Liverpool.—The Tramways committee have had before them a report from Mr. A. Bromley Holmes, the electrical engineer, as to the re-construction of certain old and the construction of new tramway lines, at an estimated cost of £143,060. It recommended that 8½ miles of lines be constructed, and that the present routes of West Derby-road, Stanley-road, Kensington and Walton-road, having a mileage of 18½, be reconstructed. The report was adopted and it was resolved that the Smithdown-road route be proceeded with as soon as possible, so that it might be completed before the end of July next. It has been decided to construct loop (electric) lines between Lord-street and Paradise-street, and at the Dingle terminus, at a cost of £4,770.

London County Council.—At Tuesday's meeting, the adjourned report of the Highways committee, on the question of the overhead wires of the National Telephone Co. at Islington, was again discussed, the committee recommending that the company be permitted to retain these wires for a certain period. Mr. Radford moved that the report be referred back. The company (he said) had not been carrying out the bye-laws for years, and was not entitled to any consideration. They knew that the company had the most costly system in the world and one of the worst. Mr. Benn (Chairman of the committee) said he would take the report back, and hoped the Vestry of Islington would communicate with the Council. Mr. Beachcroft, at a later stage, asked if it was a fact that 900 persons in London were unable to get telephones owing to the Council refusing consent to the National Telephone Co. to lay underground wires. Mr. Benn said it was perfectly true that certain consents had been withheld by the Council because the company would not consent to concede to the Council terms which they had conceded to other cities. They regretted the inconvenience caused to people who were prepared to pay the high rates, and they had arranged to meet the representatives of the Company in order to see what could be done. The delay was, however, caused by the company refusing to concede the concessions they should.

Long Distance Telephony.—Rapid progress is being made with the telephone line between Berlin, Brussels and Paris, which, when completed, will be 621 miles long, and the most important in Europe.

Manila.—There will probably shortly be an immense development of the Philippines, and in Manila especially, there already exists opportunities for trading in electric plant and apparatus. One electrical plant of Spanish manufacture is already installed, and there is a telephone exchange service available. There are a large number of cigarette and rope factories, some employing as many as 4,000 hands. A tramway worked partly by steam and partly by horses is also running. A large part of the trade of Manila is in English hands, and the change over from horse traction to electric and of the primitive methods of driving in many of the factories in Manila (especially the rope factories) for electric methods afford a good opening for electrical enterprise. There are 7,000,000 people in the Philippine group.

Marylebone (London).—The Metropolitan Electric Supply Co. have replied to the Vestry on the subject of the purchase by that body of the portion of the company's undertaking situate in the parish of Marylebone, and asking (as the Vestry give notice of their intention to apply for compulsory powers to purchase and also powers to enter into competition with the company) for further information with regard to the proposed basis of negotiations. The Electric Lighting committee are considering this communication. At last night's meeting of the Vestry Mr. G. B. Crook had a motion on the paper asking for information regarding the actual powers possessed by the Metropolitan Co. so far as the parish of St. Marylebone was concerned. He, however, asked leave to withdraw this resolution.

Morecambe.—The electrical engineer (Mr. C. F. Parkinson) has been instructed to report upon the proposal to extend the electric light mains to Bare. Messrs. Stoddart and Co., who have submitted a scheme for wiring premises in the district on the easy payment system, have been requested to supply additional details.

Musselburgh.—The Town Council have decided to consult Mr. W. A. Bryson, the Leith burgh electrical engineer, as to establishing electricity supply works.

National Telephone Co.—Particulars are published of bills to be presented to Parliament by the National Telephone Co. Bill No. 1 seeks powers to dissolve the present company and to cancel its memorandum and articles of association, to re-incorporate the shareholders into a new company, and to vest in the new company all works, plant, rights, powers, privileges, licences, wayleaves, &c., &c., belonging to the present company; to re-arrange the capital, provide additional capital, and to give various powers to the new company in connection with the opening of streets, acquisition of licences from the Postmaster-General, &c. Bill No. 2 seeks powers to confer upon the new company such rights and privileges as may be necessary for the purpose of effectively providing telephonic communication throughout the United Kingdom, the Channel Islands, and the Isle of Man.

Northallerton (Yorks).—Mr. J. E. Hutton appeared before the District Council last week to present his proposal for the electric lighting of the district. A company has been formed to establish electricity works, and Mr. Hutton now formally asked for permission to carry out this scheme, which was granted.

Portsmouth.—The Town Council have decided to give the Provincial Tramways Co. 12 months' notice of their intention to purchase the local tramways.

Perugia (Italy).—The municipal authorities of this town have entered into arrangements with the Siemens and Halske Aktien Gesellschaft, of Berlin, for the erection of electricity supply works.

Presentation.—A presentation has been made to Mr. J. H. Lee, late borough electrical engineer at Southampton, by the members of the Electric Lighting committee and staff. Ald. Bone, who made the presentation, spoke very highly of Mr. Lee's connection with the committee of which he was Chairman, and regretted that Mr. Lee was leaving the town.

Rawmarsh.—The District Council have appointed a special committee to consider and report upon putting the provisional order into force.

Sleaford.—The Tradesmen's Association urge the District Council to call in an electrical expert to report on the advisability of putting down electricity supply works.

Southport-Lytham Electric Tramway.—The Southport Town Council have expressed their approval of Mr. Wood's scheme for the construction of this tramway. The proposed line, which would be constructed on the Brighton and Rottingdean system, is estimated to cost £300,000, and a provisional order will shortly be applied for.

Speed of Electric Trams.—Sir F. Marindin opened an inquiry at Dublin, on Wednesday, into the application of the Dublin United (Southern District) Tramway Co., for permission to increase the speed of the tram cars on the Dublin-Dalkey route. A mass of evidence was given in support of the application, and most of the witnesses favoured an increase to 12 miles an hour. The inquiry was adjourned for further evidence.

Stretford.—A meeting of ratepayers has condemned the proposal of the District Council to establish municipal electricity supply works as it is thought that current could be obtained at a cheaper rate from the Manchester Corporation. The council's consulting engineer (Mr. R. P. Wilson) has advised the erection of independent generating plant.

Stockport.—The Stockport and Hazelgrove Tramways Co. (Limited) has been approached by a London syndicate with a view to the purchase of their undertaking. The syndicate offer a sum of £40,000, the amount recently tendered by the Corporation.

Digitized by Google

It is probable, however, that the Corporation, who are anxious to introduce electric traction, will be able to come to terms with the company. A bill dealing with electric traction is being promoted by the Corporation.

Tamworth, (N.S.W.).—An electric lighting scheme has been prepared for the Municipal Council of this district by Mr. J. O. Callender, of Sydney. The scheme, which involves the utilisation of the power available in the service reservoir of the waterworks, is estimated to cost £5,560.

Telegraphic Communication in Egypt.—The Berber-Suakin telegraph line having been completed, telegraphic communication is now available between Cairo and Suakin and Kassala, over the Egyptian and Suakin lines.

Telephone Municipalisation.—The National Telephone Co. are endeavouring to arrive at an understanding with the Glasgow Corporation as to improvements of the local telephone service, and at the same time to meet the views and objects expressed by the Corporation in the course of the recent inquiry. The company propose to make the minimum charge £6 per annum for each instrument with a maximum of 500 conversations, any excess to be charged on a fixed scale. In return for these concessions the Corporation are asked to withdraw their objections to the granting of wayleaves, &c.

A special meeting of the Parliamentary Bills committee of the Glasgow Corporation was held last week for the purpose of adjusting the clauses of the bill for power to establish and work a telephone exchange system in Glasgow. In the course of the discussion the town clerk (Sir J. D. Marwick) questioned the legality of the common good being included in the bill as a guarantee for the scheme, maintaining that only the rates could be used for that purpose. It was pointed out that the common good had been similarly pledged in connection with the tramway scheme, but Sir James was obdurate. The committee were equally emphatic, and the result was that Sir James absolutely refused to have anything to do with the bill or to allow his name to be appended to the notice in the usual way. The committee, in the circumstances, decided to ask their London agents, Messrs. Beveridge, to attach their names to the notice in terms of the Act of Parliament, and to promote the bill.

Mr. William Thomson, of the Mutual Telephone Co., Manchester, dealing with the question of the probability of the company obtaining a licence from the Postmaster-General, writes:—

"At the present moment the question of granting a licence to the Mutual Telephone Co. is under the consideration of the Treasury, and I feel sure that if Manchester will fairly represent the position of the telephone question here a licence will be granted. The Mutual Telephone Co. was formed by reason of, and in accordance with, the terms of the Treasury minute which stipulates for competition only by private companies, and as a large amount of time and money has been spent by the few on behalf of the many in the town and district it is to be hoped that Manchester will not be satisfied with any attempt to repudiate the telephone Treasury minute and to ruthlessly sweep away all that has been done by those who formed the Mutual Telephone Co. The recent Select Parliamentary Committee expressed the opinion that competition should be commenced immediately, and the only objection which Mr. Hanbury had to private companies was that they might be bought up by the present licensees. This can be prevented by an undertaking which this company is willing to give. The Corporation cannot commence a telephone exchange for a year or two from now, whilst the Mutual Company can commence operations immediately, and as it is willing to transfer its plant and business at any time to the Corporation or to the Post Office under conditions which can be arranged before the licence is granted, it is difficult to see any reason for withholding the licence from it, especially as it would save Manchester people at least £20,000 per annum and give an increased and more efficient telephone service to the city and district."

The Bedford Town Council have decided to repeat their application to the Postmaster-General for a telephone licence.

Wednesbury.—The Town Council have retained Mr. F. J. Warden-Stevens as consulting electrical engineer.

West Australian Tariffs.—Under a new Customs tariff, to be levied on certain goods imported into Western Australia, machinery of all kinds will bear a 3 per cent. *ad valorem* duty, and parts of machinery 10 per cent.

Whitchurch (Salop).—A meeting of ratepayers has rejected a proposal to purchase the gas works at £37,000, as it is considered that electricity supply works could be erected at less cost.

Wigan.—At a recent meeting of the Electric Lighting committee the deputation recently appointed to inspect the electricity works at Leeds, Bradford and Wakefield presented a preliminary report in which they recommended the erection of electricity supply works. The Committee were, however, instructed to prepare and present a complete report on their visit for the instruction of the Council

Willesden.—The electrical engineer (Mr. E. T. Ruthven-Murray) has selected a site for the proposed electricity station at Lower-place, between the London and North-Western Railway and the Grand Junction Canal. The Local Government Board are to be asked for sanction to a loan for the wiring houses.

Woking.—The purchase of the undertaking of the Woking Electric Supply Co. is under the consideration of the District Council.

Workhouse Lighting.—The Shoreditch (London) Guardians have decided to borrow £2,000 for the electric lighting of the workhouse.

Electro-Harmonic Society.—Members are reminded that a "ladies' night" entertainment will be given at the St. James's Hall Restaurant this (Friday) evening, at 8 o'clock.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Co. (Limited).

The fifty-fourth ordinary general meeting of this Company was held on Wednesday, under the presidency of Mr. CHARLES W. PARISH.

The SECRETARY (Mr. James Scott) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the Board are glad to be able to present to you such a satisfactory report, notwithstanding the anxious period through which we have passed since our last meeting. You will recollect that the insurrection which broke out in the island of Cuba in February, 1895, was in full force at the commencement of this year, and its continuance led to the outbreak of the Spanish-American war in April last. On the outbreak of hostilities, the American Government practically took control of the cables of the Western Union Co. at Key West (an island between Havana and Florida), and instituted a strict censorship over all messages, none being allowed to pass in cypher. This compelled the Spanish authorities at Havana to send their government messages *via* Santiago and Jamaica to Spain, instead of by the usual route through America, and this also applied to the messages which business firms in Havana preferred to send *via* Santiago instead of through America. This unexpected diversion of traffic caused a considerable increase in the receipts of our Company; in fact, many messages from Havana were carried over the whole length of our system which, under normal circumstances, would not have touched our lines at all. The American authorities then set to work to isolate Cuba as far as possible from the outside world, and also the chief towns one from the other where cable communication existed, and with the unfortunate result that many of our cables were cut, while our cable hut at Cienfuegos was entirely destroyed by the bombardment of the American fleet. It is with a feeling of pride and satisfaction, in which I am sure you will sympathise—that I can tell you that our staff kept to their posts under most trying circumstances, and that, as a matter of fact, they were able to maintain communication from Havana to Jamaica right through the war. When the Americans entered Santiago, after the capitulation on July 17th, they were greatly surprised to find our cables still working, but on hearing that they belonged to an English company they contented themselves with sealing them up, which stopped all our through traffic for about three weeks. At Santiago and Manzanillo our representatives were able to do real service in the cause of peace by keeping to their posts during all the dangers of bombardment by the American fleet; in fact, all our staff passed through a most trying experience with a high sense of duty, which I am glad to say has been recognised both by the Spanish and American generals. We arranged that they should have an increase of pay to meet the special circumstances in which they were unfortunately placed, as the price of living rose to an abnormal level. Since the termination of hostilities we have been able to repair the damaged cables with the exception of the Cienfuegos-Casilda section and the 1891 Cienfuegos-Batabano cable. The breaks in these two cables appear to be in deep water, and will need a regular cable steamer to put them in order, and we are now arranging to send one out. Directly we learnt of the damage to our property we put ourselves in communication with the Foreign Office, and asked for their assistance to claim suitable compensation from the American Government, and we propose to give in a regular claim as soon as we know the total cost of the repairs. I am sure our Foreign Office will do what they can to assist us consistent with international law, but I cannot yet tell you that our claim will be admitted. I rather like to make a point of that, because I know that some of the shareholders think that we have only to appeal to the Foreign Office to ask the Americans to pay us when we shall be paid at once, but I rather doubt that. It will take some time before we are paid even if our claim is recognised. Since the cessation of hostilities, and in view of the change of government in the island, the position of our Company in regard to its concessions and subsidy has received the best attention of your Board, and we have taken steps to bring before the United States Government the rights of the Company in order that they may receive formal recognition. We have every hope that this recognition will be duly secured. I may remind you that the subsidy which we have for the cable to the towns south of the island is in the form of a charge on the Havana treasury. Before turning to the accounts I wish to explain that, owing to the complicated way in which our rates are now calculated on what is called a mileage basis, instead of on a fixed tariff, we cannot satisfactorily continue the system of estimating the receipts for the two last months of each half-year (which has been our custom for many years), and before presenting to you the accounts in future we shall have to wait for the detailed returns from Cuba. We shall aim, therefore, at issuing the half-yearly accounts in April and October, and the meetings will be held as soon after as possible. The accounts for the half-year show a gross income of £33,504; expenditure, £8,091. We commenced the half-year with a reserve fund of £106,000, and have drawn from this £11,553, as the balance of cost of the Manzanillo-Santiago cable, and repairs to the

Digitized by Google

Cienfuegos-Santiago cable of 1881. We are now able to place to reserve £15,553, bringing it up to £110,000 to June 30th last, against £118,000 to June 30, 1897. We propose to pay the Ordinary shareholders 3 per cent. for the half-year and a bonus of 2s. per share. We have adopted this method because our increased receipts have come altogether from a special source not likely to ever occur again. I now propose—

"*That the report and accounts for the half-year ended June 30 last, now submitted, be received and adopted.*"

Mr. GEORGE KEITH seconded.

Mr. WILLIAM HANNAY: May I ask about your remark as to the subsidy to the cable of the Company falling on the Havana Government, whether that means that it will be continued to be paid or that the Company will have no claim on it in future?

The CHAIRMAN: We shall be exceedingly disappointed if we lose our subsidy. At present we see no chance of that.

In answer to further questions as to the arrangements with the United States for the payment of damages to the Company's cables, and as to whether the United States or the Spanish authorities would be the parties to grant an extension of the concession,

The CHAIRMAN said he could not answer the question as to what was going to happen in Cuba, or who was to be the ruling power there. As to the future prosperity of their Company, he must remind the shareholders that whereas they used to receive 5s. 2d. for every word telegraphed to Jamaica, it is now only 3s.

The report was then adopted unanimously. Dividends at the rate of 10 per cent. per annum, less tax, on the Preference shares, and 6 per cent. per annum and a bonus of 2s. per share, tax free, on the Ordinary shares, were approved. Mr. Alexander Graham Low was re-elected a Director, and Messrs. Gane, Jackson, Jefferys and Wells were appointed auditors.

A vote of thanks to the Chairman, Directors and staff terminated the proceedings.

Yorkshire House-to-House Electricity Co. (Limited).

An extraordinary general meeting of this company was held on Monday to ratify the provisional agreement for the sale of the undertaking to the Leeds Corporation. The Chairman (Mr. Grosvenor Talbot) said they had met to take one of the final steps towards handing over their undertaking to the Corporation, under the inexorable terms of the act and provisional order which called the company into existence. He gave a sketch of the steps taken by the Corporation for the acquisition of their undertaking, particulars of which have been given from time to time in *The Electrician*. By Clause 1 of the final agreement the Corporation accepted the accounts as passed by the Board of Trade auditor up to 1897. This, he thought, was a wise step on the part of the Corporation. Clause 2 was the clause for the appointment of the capital account. This account had been taken in this way:—All goods and machinery which had been delivered, if not paid for, went into the capital expenditure. In addition with goods that had been manufactured under contract or order of the company, but not completed, such part as had been finished, and was in the works of the contractors on August 31st, would also be included in the amount properly expended on capital account. He thought this was a reasonable and liberal arrangement for the adjusting of the capital expenditure. It did away with a great deal of difficulty, and would make it much more easy to come to the final division. Clause 3 dealt with the depreciation which they had been in the habit of allowing every year under the direction of the Board of Trade and under necessity. This would still continue for the few months of this year that they were working on their own account. Clause 6 provided that the company should have no claim in respect to back dividends in order to make up the aggregate 5 per cent. They had a divided opinion as to whether that would be allowed or not. They were advised that they had no claim because they had already put £8,000 by for equalisation of dividend, which might have been used to pay dividends. Moreover, this was a point upon which the Corporation would have gone to law. The whole arrangements would have been broken off; everything would have had to be begun again *de novo*, and the affair arranged under the Court of the Board of Trade. This being so the Directors decided that the point was not worth standing out for. The Directors thought the agreement was one they could recommend to the shareholders as a desirable arrangement, and the best possible way they could bring this matter to a conclusion. The negotiations had been carried on throughout, with a desire that an amicable and fair result should be arrived at. The arrangement to wind up the company under a provisional order, rather than the bargain first suggested, they believed to be a wise one. He believed the ratepayers could have no cause of complaint against the company, and the shareholders could have no cause for a moment to feel that their interests have been sacrificed. It was a satisfaction to know that in handing over their business to the Corporation, Leeds would receive the concern in a high state of efficiency, a full career of prosperity, and capable of almost indefinite expansion. The agreement was unanimously approved.

Hampstead Electric Supply Co. (Limited).

We understand that the first (statutory) meeting of the shareholders of this Company was held on Monday last at the Westminster Palace Hotel, Victoria-street, Westminster, S.W., under the presidency of Mr. J. SOARES. As the report of the proceedings appears as an advertisement in several of the London daily papers, it is to be presumed that the particulars have been supplied by the Company. We publish the following abstract without accepting any responsibility for its accuracy. The customary invitation for the representative of *The Electrician* to be present to take a note of the proceedings was not received:—

The CHAIRMAN said: This meeting is only a formal one, at which it is not possible, as a rule, for the Directors, who have practically only just got into harness, to give much information as to the past working of the Company; but we nevertheless have much pleasure in putting before you as much information as possible at this early stage of the Company's existence. You will remember that in the prospectus we gave prominence to the very important fact that our Company is in the strong position that it cannot be interfered with by the local authorities in the way of compulsory purchase. This is so, and this fact alone should considerably add to the value of the shares from the point of view of the investor. There is less speculation in the holding of shares of an established undertaking, the goodwill of which has not to lapse at the end of a certain number of years, as is the case with most other electric lighting companies. The great advantage which shareholders in electric lighting companies have over shareholders in other industrial concerns is that their profits not only do not fluctuate but necessarily increase each year of the Company's existence. You will also remember that at the date of the prospectus we had in operation the respectable figure of 33 miles of mains. This, of course, has now been considerably added to. To go further into figures, and taking the latest information available, the increase in the number of houses supplied since March 31 is no less than 168, and there are contracts in hand for connecting with 400 more. These figures speak volumes for the increased and increasing prosperity of your Company. I think it also well to state that since the issue of the prospectus we have materially added to the electric lighting plant, and it is now even in a higher state of efficiency than when Prof. Silvanus Thompson testified to its excellent condition. We shall shortly have in operation two additional boilers, these being necessary to cope with the rapidly-increasing output. We anticipate that we shall soon require to make still further extensions, and without in any way interfering with our existing premises I may state that the land beyond the boilerhouse is available, without further cost, for the erection of a range of five more boilers; in fact, the unoccupied land will suffice for at least 1,000 kilowatts more, and then, as you know, in addition to this we have the very valuable premises of Messrs. Taylor and Lowns, whose business is a most profitable and progressive one. Those of you who reside in the large area covered by our Company in Hampstead must have observed that in the main road, almost adjoining the Finchley-road Railway Station, and in close proximity to this Company's central supply station, a large store (to be conducted, I believe, on similar lines to John Barker and Co. and Harrod's Stores) is in course of construction and is shortly to be opened. We are in treaty for the supply of electric current not only for the lifts, but for the electric lighting throughout. There is also another and larger undertaking of a different character in the neighbourhood, for which we hope to obtain a contract. We have, of course, adequate working capital for the extensions and for undertaking these large contracts. Perhaps I have gone more fully into the affairs of the Company than is usual at a statutory meeting, but I consider that shareholders should always be taken into the confidence of the Directors when possible, and I have now only to assure you that the Board will always be unremitting in their endeavours to promote your interests and to justify the prospects referred to in the prospectus. I may add, in conclusion, that the brokers to the Company will be instructed to apply for a special settlement and quotation of the Company's shares.

Mr. E. T. READ proposed a vote of thanks to the Chairman for the satisfactory statement he had given to the shareholders. He said he had lived in Hampstead all his life, and he knew very well what an immense prospect there was of expansion, and he had no hesitation in saying, from his knowledge of the neighbourhood, that this Company, if properly managed, would be one of the most prosperous electric lighting companies in the country. The outlook for the supply of motor-cars for the tradesmen in the neighbourhood was also very bright, and by being able to get rid of their day current in that way they would be enabled to supply the electric light at far cheaper rates than other companies could do at present.

The motion was carried unanimously.

NEW COMPANIES, STATUTORY RETURNS, &c.

CRYSTAL PALACE LIGHT RAILWAYS AND TRAMWAYS CO. (LIMITED). This company has been registered, with a capital of £5,000, in £1 shares, to carry on the business of railway, tramway, omnibus, carriage and van proprietors, electrical engineers, carriers of passengers, goods, &c.

HIMALAYA ELECTRIC RAILWAY (LIMITED).—This company was registered on Nov. 15, with a capital of £2,000, in £1 shares, to acquire and develop an invention known as the Himalaya Electric Railway, and a railway and accessories erected under the said invention at the New Brighton Tower Grounds. The first subscribers (each with one share) are:—P. Violi, Mrs. A. Violi and G. Spagnuoli, engineer; W. Turner, H. Hodson, H. A. Sewards, and R. H. Davey.

TOURTEL MANUFACTURING CO. (LIMITED).—This company was registered on Nov. 9 with a capital of £18,000, in £1 shares, to acquire the English business of engineers and meter apparatus manufacturers, now carried on by the Tourtel Gas and General Engineering Co. (Limited), and to carry on the business of electricians, electrical engineers, suppliers of electricity, electrical apparatus manufacturers, mechanical engineers, &c. The first subscribers (each with one share) are: Arthur F. Davies, F. S. Springell, J. M. Tourtel (engineer), D. H. Davies, C. E. Smith, M. Sharpe and G. T. Stebbing. The first Directors are: Arthur F. Davies, J. B. Rombach and J. M. Tourtel.

CECIL WRAY AND CO. (LIMITED).—This company was registered on Nov. 17, with a capital of £3,000, in £1 shares, to acquire the business carried on by Cecil W. Baxter and Cecil May, as manufacturing opticians, electricians, electrical engineers, &c. The first subscribers (each with one

Digitized by Google

share) are :—T. Middlebrook, J. H. Oulton, J. Oulton, G. B. Russell, Mrs. E. Wray, W. T. Sykes and W. Wray.

CAMBORNE ELECTRICITY SUPPLY CO. (LIMITED).—The statutory return to Oct. 9 gives the capital as £10,000, in £1 shares, of which seven have been taken up and paid for in full.

ELECTRICAL POWER DISTRIBUTION CO. (LIMITED).—The statutory return to Nov. 1 has been filed. The capital is £20,200 divided into 2,000 shares of £10 each and 200 shares of £1 each; 154 of the former and all the latter have been taken up. £3 per share has been called on the £10 shares, and the full amount on the others.

MACKEY'S ELECTRIC LAMP CO. (LIMITED).—According to the statutory return to Oct. 13, the capital is £2,000, in £1 shares, of which seven have been taken up and paid for in full.

SANDGATE AND HYTHE ELECTRIC CO. (LIMITED).—The statutory return to Oct. 24 has just been filed. The capital is £1,000, in £10 shares, of which seven have been taken up, but no calls have been made.

WERNER CADMIUM ELECTRIC ACCUMULATOR SYNDICATE (LTD).—The statutory return to Oct. 2 gives the nominal capital as £6,000, in £1 shares, of which 4,515 have been taken up. The full amount has been called and paid on 415 shares, and 4,100 shares are considered as paid.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27$\frac{13}{16}$d. per oz. (Nov. 24). Consols (2¾ per cent.) 110½—110¾ for money, 110⅝—110¾ for account; 2½ per cent. 104¾—105¼ (Nov. 24), Stock Exchange Settling Days: Consols, Dec. 1; Stocks and Shares Continuation Days, Nov. 28 and Dec. 13; Ticket Days, Nov. 29 and Dec. 14; Pay Days, Nov. 30 and Dec. 15; Mining Share Carry-over Days, Nov. 26 and Dec. 12.

BRITISH COLUMBIA ELECTRIC RAILWAY CO. (LIMITED).—During the week this company invited subscriptions for 12,000 non-Cumulative Five Per Cent. Preference shares of £10 each at £11. The company has an authorised capital of £370,000, of which the Ordinary shares (£200,000) have been issued. There are in addition £250,000 Four and a-half Per Cent. First Mortgage Debentures and £60,000 non-Cumulative Six Per Cent. Income Bonds. Some further reference is made to this company's undertaking on another page.

CRYSTAL ELECTRIC LAMP AND ROSE AND BIRD (LIMITED).—We are informed that at the statutory meeting of this Company on 10th inst., the Chairman congratulated the shareholders on the satisfactory increase in the orders received since the amalgamation. The factory at Bedford was working at full pressure, and in order to cope with old customers' increasing demands and the new connection the Directors had been compelled to increase the apparatus and machinery. The Company had one of the best, if not the best, lamp factories in the kingdom, replete with every modern improvement, and they had 500 customers, including the Admiralty, War Office, Post Office, several railway companies, the London County Council, and numerous corporations, and most of the electricity supply companies and large contractors.

DORMAN, LONG AND CO. (LIMITED)—A profit of £74,623 is reported on last year's working, which, with balance brought forward, makes £90,101. A dividend of 8 per cent. is declared, against 6 per cent. in 1896-97, 4 per cent. in 1895-96, and *nil* in each of the two preceding years. £26,601 is carried forward.

ELMORE AMALGAMATION.—There is shortly to be an amalgamation between Elmore's Patent Copper Depositing Co. (Limited), Elmore's Wire Manufacturing Co. (Limited), and two other companies in the Elmore group. We are informed that a large working capital is to be provided.

RICHARD HORNSBY AND SONS (LIMITED).—The Directors' report states that there was a profit of £37,827 on the year's working. There is a disposable balance of £29,637, and the Directors recommend a dividend on Preference stock at 6 per cent. (including arrears) and a dividend at 6s. per share on Ordinary shares.

MIDDLESBROUGH TOWN AND LANDS CO. (LIMITED).—At the annual meeting of this company the Chairman (Major W. T. E. Fosbery) said that the subsidiary Electric Lighting Company was making fair progress and paying its way. They offered to the shareholders of that company 10 per cent. of the face value of their shares in debenture stock, and this was accepted to the amount of £7,150 worth of shares, so that they had issued £715 of debentures in that way, and the Town and Lands Company hold in that company something more than half of the issued capital.

PERTH (WESTERN AUSTRALIA).—The work of constructing and equiping of the Perth Electric Tramways (Limited) is being pushed forward; rails, sleepers, blocks, &c., have been ordered; the permanent way is being prepared, and the fencing round the power-house commenced. The engineers, Messrs. J. G. White and Co., New York, expect to open the first section for working by May 31 next.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange committee to appoint a special settling day in and to grant a quotation to 100,000 £1 fully paid Ordinary shares of the Blackheath and Greenwich District Electric Light Co. (Limited), and £100,000 Five per Cent. Perpetual Debenture stock of the British Electric Traction Co. (Limited).

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Nov. 18 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £2,870.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended Nov. 15 is £2,966, against £2,093 in the corresponding period of 1897.

NOTES.

THE official inquiry has placed beyond a doubt that the lamentable disaster to the "Mohegan" was not due to any aberration or inaccuracy of the compass. Now that the full facts are known, it is no longer necessary to point out that the ship was wired on the two-wire system, that the dynamos were 100ft. distant from the compasses, and that there could be no local deviation of the compasses of sufficient magnitude to produce so serious an error in the course; for the evidence before the Court of Inquiry has clearly established that the course, W. by N., was intentionally steered by the man at the helm, the following of which course after passing the Eddystone would undoubtedly lead in the direction of the Manacles.

THE judgment of the Court conveys one useful lesson, however. There was a serious error in having all the lights of the ship controlled directly from the dynamo. The use of oil lamps, kept trimmed and ready for use in case of accident, proved an insufficient reserve, and, had the lamps been ready lighted, as the Court now recommends, there might have been time to put them in position. It would be an improvement to light the masthead light and a few other lamps of almost equal importance by means of secondary batteries, so that they would continue to burn whatever happened to the machinery. The batteries for these few lamps would be of such small size that their weight would be of no consequence. In a disaster of this kind it is inevitable that the dynamo should stop running, and it is undeniable that the unfortunate loss of life would have been less had it not been for the extinction of the lights.

WHEN the model form of Electric Lighting Provisional Order was recast in 1889, in consequence of the passing of the Act of the previous year, the London County Council obtained certain special privileges not accorded to County Councils in the provinces, and consequently in the London form of order its name appears in several clauses where, in the opinion of many people, it might with advantage have been left out. One of these provisions peculiar to London requires notice to be given to the County Council, as well as to the Local Authority, before laying mains or carrying out other works in any street, and gives powers of objection to both bodies. As the streets of London are, except in a few cases, under the control of District Boards as Local Authorities, and not of the County Council, it is difficult to understand why the latter should have anything to do with the matter; but since the Orders framed by the Board of Trade and confirmed by the Legislature have accorded this privilege, presumably it must be on the ground that the Council has some interest distinct from that of the Local Authority. The manner in which the privilege has been exercised by the Council in giving consent to works in streets not under its control seems to have given some umbrage, which has been noticed in our columns in the cases of the districts of Lewisham and Bermondsey, where the Local Authorities appear to object to works in their streets being approved by the County Council without previous consultation with them. On the assumption that the Council has a separate interest in such streets, it is, of course, entitled to act on its own initiative without consulting the Local Authority, who still have their say in the matter; but at the same time it is not unnatural that the legal guardians of the streets should be unable to appreciate, any more than we do, what interest the County Council in fact has, and should take every opportunity of expressing this feeling.

WHATEVER fault may be found with the managers of the National Telephone Co., they cannot be accused of not knowing their own mind, or of lacking courage to back it up. The three Parliamentary Bills which they have given notice of their intention to introduce in the ensuing session embody not only a distinct policy, but a direct challenge to Postal and Municipal authorities. The policy of the Company is evidently to make a big fight for its existence by strengthening its hands in all directions, of which perhaps the financial changes are the least important. Nothing short of powers

Digitized by Google

equal, if not exceeding, those exercised by the POSTMASTER-GENERAL will satisfy the Company; and the creation of a Court of Appeal to deal with the obstructive tactics of local authorities is intended to rid the Company of its most troublesome opponents. If these Bills, or even any considerable portion of their far-reaching provisions, should by any chance pass the ordeal of Parliamentary inquisition, truly the Company will have gained a position that will be practically unassailable.

OF the financial part of the scheme, we need say nothing, its object being perfectly plain, and, in the circumstances, quite legitimate from the Company's point of view. The Government will probably regard it from their point of view, as being part and parcel of the general scheme, and will oppose it or accept it according as they may, by that time, have made up their minds what their own future policy is to be. Not unlikely the Company's immediate aim is to force the pace, and compel the Treasury to come to some working understanding with the Post Office that will let the Company know exactly how it stands. But on its merits alone the application for additional powers is both reasonable and expedient. Virtual monopoly though it is, the National Telephone Co. is a monopoly without any powers whatever, the result being that the public is badly served because the public itself, either individually or by its representatives, hinders the Company from serving it well. The situation is intolerable, and the best way of escape would be for the Post Office either to assume the business itself, or to exercise the powers it possesses on behalf of the Company. The Post Office can obtain fresh and enlarged powers if it wants them; it is very doubtful whether the Company can.

A Correction.—We are concerned to find that Messrs. Macartney, McElroy and Co., of Glasgow and London, were incorrectly stated (in our description of the Glasgow tramways in *The Electrician* of November 18th) to have carried out the overhead construction of these tramways as sub-contractors to Messrs. R. W. Blackwell and Co. We are now informed that Messrs. Macartney, McElroy and Co. were the actual contractors for the whole of this work, and erected and supplied all the overhead material with the exception of one or two minor details.

Cable Interruptions.—

	Date of Interruption.
St. Louis and Noronha	Oct. 17, 1898
Para—Maranham.....	Nov. 15, 1898

Distribution of Prizes.—We are informed that Mr. W. H. Preece, F.R.S., has consented to distribute the prizes at the Merchant Venturers' Technical College, Bristol, on Wednesday, December 21st.

The Electrical Engineers R.E. (Volunteers).—The following promotions are announced:—E. Rorke (sapper) to be quartermaster sergeant, 13 sappers to be promoted to the rank of sergeant, and 14 to the rank of corporal.

Long-Distance Telephony.—A correspondent telegraphs to *The Times* from Little Rock, Arkansas, U.S.A., that successful telephone communication has been established between Little Rock and Boston, a distance of 1,900 miles.

The Institution Annual Dinner.—The Secretary has reminded us that members who wish to attend the annual dinner of the Institution of Electrical Engineers, on December 7th, should apply for tickets to-day or to-morrow.

Institution of Electrical Engineers.—We are informed that candidates for election to the Institution who wish to be admitted under the existing rules should send in their applications before Monday next, December 5th, if they seek election as members, or, if as foreign members, associates or students, before Thursday next, December 8th.

Underground Railways for Berlin.—An extensive system of underground electric railways is to be built in Berlin. It is intended to place them only a few feet below the surface of the roadway, and they will resemble in that and several other respects the subway railway in Budapest, described in *The Electrician*, Vol. XXXVIII., p. 55.

The Late Dr. John Hopkinson.—At the meeting of the Institution of Electrical Engineers, on November 24th, letters were read from the American Institution of Electrical Engineers and the South African Society of Electrical Engineers, expressing sympathy with the loss the Institution had sustained in the death of Dr. John Hopkinson.

Obituary.—We regret to announce the sudden death of Mr. Charles H. Summers, chief electrician of the western division of the Western Union Telegraph Co., at the age of 61. Mr. Summers had been connected with the American telegraph service since 1854, when he was engaged as an operator on the old Pittsburg, Cincinnati and Louisville line.

Municipal Telephony.—The Secretary to the Post Office has sent the following letter to the Town Clerk of Bedford:—

I am directed by the Postmaster-General to acknowledge the receipt of your letter of 21st inst., enclosing a copy of a resolution passed by the Corporation of Bedford, applying for a license to transact telephone exchange business, and to state, in reply, that he is unable to accede to your request, as he is advised that municipalities are not empowered to work such business.

This time there is no promise of a licence if Parliamentary powers be obtained, a simple refusal being apparently deemed all that is necessary.

Electric Light in Gasworks.—The town of Longton (Staffs.) has no public electricity supply, but it can boast at least of one private electric lighting plant—viz., at the gasworks. Current is generated for lighting the purifier house, the governor house, engine room, manager's room and offices. The plant consists of a 110-volt continuous current dynamo, and is capable of supplying sixty 16-c.p. incandescent lamps. It has already proved itself eminently useful in enabling the purifiers to be attended to at night on the occasion of a breakdown. We may add that Longton's name figures in the list of Corporations applying for electric supply power next session.

The Telegraph in South Africa.—The following particulars of the condition of the telegraph system in Rhodesia and South Africa generally have been sent by a correspondent to the *Telegraph Age*:—The alphabet and system of working are exactly the same as those used in England, while the majority of the operators are also English. All the lines are worked on the open circuit principle with tape instruments, relays not being used. In some districts iron poles have been substituted for wooden ones, on account of the white ants, who have a way of eating the bottom parts of the poles, and causing their collapse. Some samples of makeshift methods of insulating are to be seen. One consists of iron spikes driven into the pole, the neck of a glass bottle being fitted on them, and the wire fastened to the glass.

The Long-Schattner Meter.—Messrs. Schattner and Co. write us that the prepayment meters they now supply work with a fall in voltage slightly lower than that given in our article last week. The maximum drop for the 100-volt 5-ampere meters is 0·6 volt, and for 200-volt meters 1·2 volts. Attempts were made to produce reliable instruments to work with a drop of 0·1 and 0·2 volts respectively, but it was found that these did not register small currents correctly. The reason is obvious. A drop of 0·6 volt across the resistance shunting the copper voltameter, when 5 amperes is passing through it, means a drop of only 0·04 volt when the third of an ampere required for a single 8-c.p. lamp is passing, and this fraction of a volt does not greatly exceed the minimum required to produce deposition in a copper voltameter. Even these meters could be cheated with a 5 c.p. lamp of fair efficiency.

Unipolar Dynamo.—The *American Electrician* suggests that by coupling a unipolar dynamo to a steam turbine, a cheap and effective machine for generating currents at low voltage could be evolved. The current-carrying capacity of a dynamo

Digitized by Google

of this type is very great, but, as is well known, when run at normal speeds its voltage is extremely small. Our contemporary assumes a speed of 30,000 revolutions per minute, and estimates that, if a disc of 30in. in diameter were employed, the "effective area which can be fluxed" would be 35 sq. in., through which it should not, it says, be difficult to thread 35,000 lines of force. An effective voltage of 1·75 would be generated, perfectly adapted to some kinds of plating work. But by increasing the diameter of the disc as much as possible without endangering it from a mechanical standpoint, a voltage of 15 or 20 is predicted, and it is suggested that two such machines in series might often prove useful.

The Royal Society.—The following is a list of the Council elected for the ensuing year:—President, Lord Lister; treasurer, Mr. Alfred Bray Kempe; secretaries, Prof. Michael Foster and Prof. A. W. Rücker; foreign secretary, Sir Edward Frankland; other members of the Council, Prof. T. G. Bonney, Capt. E. W. Creak, Prof. D. J. Cunningham, Prof. James Dewar, Prof. William D. Halliburton, Prof. William A. Herdman, Mr. Victor A. H. Horsley, Dr. J. Larmor, Prof. N. S. Maskelyne, Sir Andrew Noble, Prof. E. B. Poulton, Mr. W. J. Russell, Prof. Arthur Schuster, Mr. Dukinfield H. Scott, Dr. G. J. Stoney, and Prof. J. J. Thomson. The Rumford medal has been awarded to Prof. Oliver J. Lodge for his researches in radiation and in the relations between matter and ether; and a Royal medal to Dr. John Kerr for his researches on the optical effect of electrical stress, and on the reflection of light on the surface of a magnetised body.

Opening of the Düsseldorf-Crefeld Light Railway.—On Nov. 10 the light railway between Düsseldorf and Crefeld and the new bridge built for it across the Rhine near Düsseldorf were officially opened. The line, which has been built by Messrs. Siemens and Halske in conjunction with the Rhenish Railway Co., of Düsseldorf, has a total length of 14 miles, the length of the track being 18½ miles. The steepest gradient is only 2·5 per cent. As it will to a certain extent carry trucks between private sidings and the State railways it has been built standard gauge. Two sizes of motor cars are used, those for local traffic being fitted with two motors of 20 H.P., while those for long distance work contain two 35 H.P. motors. A power station of 360 kilowatt capacity furnishes current to the overhead line, and an accumulator sub-station has also been erected containing two batteries each of 118·8 kilowatt capacity. A speed of 25 miles an hour will be attained on some sections of the line. We are indebted to the *Elektrotechnische Zeitschrift* for the above particulars.

Mica Discoveries in India.—The annual report of the Geological Survey for India contains an interesting account of Mr. T. H. Holland's recent explorations in Coorg. The discovery of pegmatites amongst the minerals of Mecara led to the institution of a careful search for mica, with the result that, in five or six localities, sheets above the average market size have been obtained. The largest were found on Elk Hill, where the outcrop of the vein is immediately beneath the soil, the sheets being quite free from warping, and measuring some 30in. in width. All the samples are of good colour, and, says the *Engineering and Mining Journal*, show a high degree of elasticity, though the value of some is reduced by the presence of ferruginous inclusions between the cleavage planes and occasional warping. The extent of depreciation in value resulting from these defects is now being ascertained in London. It seems extremely unlikely that the best veins should have been struck first in such a completely soil-covered area, but there is sufficient evidence that the mica-bearing pegmatites extend over a wide area, and, if worked with discretion, should be a source of considerable profit.

Electric Dumb Waiters.—The new public library of the city of Chicago is equipped with a system of dumb waiters, operated by electric motors, for delivering books from one department to another. Most of these waiters, says the *Electrical Engineer* of New York, travel simply in a vertical direction like an elevator, though some have recently been put in that travel in a variety of angles. The vertical dumb waiters are controlled from any floor by the movement of a pointer on a semicircular dial. The pointers on all the floors are connected together mechanically, so that if one of them is moved, all move. These pointers are intended to be moved by hand. If an attendant on the fifth floor wants the waiter at his floor, he moves the pointer to 5, and if all is right the waiter comes to his floor. If he wants to send it to the first floor, he moves the pointer to 1, and so on. To avoid confusion and accidents, the controller of the waiter motor is always locked when any door to the waiter shaft is open. The motors are arranged so as to avoid the necessity of counter-weights. They are series wound, about 1 H.P. in capacity, and run when at full speed at the rate of about 500 revolutions per minute. Being of such small power and low speed, no starting resistance is used with them, but the current is snapped on at full voltage. In order to prevent these series wound motors from running away with the car going down heavily loaded, part of the current is shunted around the armature through a resistance. This, of course, has the effect of so increasing the field strength by the greater volume of current passing through the fields that the counter electromotive force of the motor is very high for a given speed, and little current can flow through the motor. When the waiter is going up the connections are altered so that part of the current is shunted by a resistance around the fields, which has the effect of weakening the field strength of the motor, reducing the counter electromotive force at a given speed and permitting the motor to run faster than with full field strength. A brake solenoid locks the armature shaft when the motor is not running, releasing the break on the armature shaft whenever current is turned through it to supply the motor.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, December 2nd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "The Sunlight Gold-Bearing Reef, Lydenburg, Transvaal," by C. B. Sauer.

MONDAY, December 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution Whitehall.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III.—"Acetylene," by Prof. Vivian B. Lewes.

SOCIETY OF CHEMICAL INDUSTRY.

8 p.m. Meeting of the London Section in the Rooms of the Chemical Society, Burlington House, when the following Papers will be read: "On Ozone and its Commercial Applications," by Col. W. J. Engledue, and two Papers by Arthur Marshall on (1) "An Improved Apparatus for the Estimation of Carbonic Acid in Minerals, &c."; (2) "The Preparation of Standard Solutions of Sulphuric Acid."

TUESDAY, December 6th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Effect of Subsidence due to Coal Workings upon Bridges and other Structures," by Stanley R. Kay. Should time permit, the following Paper will be read: "The Ventilation of Tunnels and Buildings," by Francis Fox.

RÖNTGEN SOCIETY.

8 p.m. General Meeting at 11, Chandos-street, Cavendish-square, when Papers will be read by Ernest Payne and Dr. Walsh on "Dermatites in Relation to Röntgen Ray Work."

THURSDAY, December 8th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Papers to be read: "Improvements in Magnetic Space Telegraphy," by Prof. Oliver Lodge, F.R.S., and, time permitting, "Telegraphy by Magnetic Induction," by Sydney Evershed.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Grand Hotel, Aytoun-street, Manchester. Paper to be read: "Superheated Steam and its Application on Steam Engines," by Paul Schou.

FRIDAY, December 9th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) "Longitudinal Vibrations in Solid and Hollow Cylinders," by C. Chree, F.R.S.; (2) "On the Thermal Properties of Normal Pentane," by J. Rose-Innes and Sydney Young, F.R.S.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Ordinary Meeting at the Westminster Palace Hotel. Paper to be read: "British Cable Tramways and their Construction," by E. A. Heath.

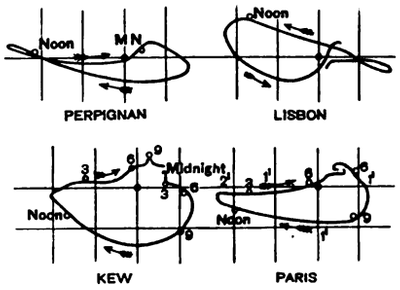
CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Temporary Magnetic Observatories.—In order to solve the momentous question whether the forces producing the phenomena of terrestrial magnetism have a potential in the earth's surface it is necessary to increase the present (diminishing) number of reliable magnetic observatories. The report presented by Prof. Von Bezold and Gen. Rykatschew to the British Association points out that the divergences from the above hypothesis are greatest between 40deg. and 45deg. of northern latitude. Since the largest number of records are available for just those latitudes, it seems probable that the apparent absence of divergences of more than 8 per cent. for the other latitudes is due to lack of material. If the phenomena of terrestrial magnetism were exclusively due to constant forces in the space outside the earth, the diurnal oscillations should be the same for any given latitude. This cannot be satisfactorily determined with the present arrangements, since there is only one observatory (Batavia) in the specially important tropical belt between 10°N. and 10°S., and only one (Melbourne) south of 35°S. The latitudes of 38°N. and 40°S. should also be narrowly watched. The report proposes the establishment of temporary observatories at Taschkent, Peking or Vladistock, Mount Hamilton, Quito, Para, Colombo, Cape Town, St. Paul and Cape Horn.

[Bezold and Rykatschew, *Terr. Mag.*, September, 1898.]

Compound Magnetic Variation Curves.—By plotting the diurnal movement of the north-seeking pole of a magnetic bar supposed to be suspended by its centre of gravity, J. B. Capello obtains curves which are distinctively characteristic of



the place where they are obtained. The diagrams (*see* Fig.) illustrate the diurnal variations of the declination and dip at Kew, Paris, Perpignan and Lisbon. It will be seen that as the latitude decreases the curves become flatter. At Perpignan a loop appears, and at Lisbon this loop is enlarged so as to present a retrograde movement. It would be useful to find some means of automatically recording such curves.

[Capello, *Terr. Mag.*, September, 1898.]

The Azores as a Magnetic Station.—In the course of his studies of the Azores Archipelago as a meteorological station for weather predictions, Prince Albert of Monaco thought that any observatories established there might be of service to other branches of science, and more especially to terrestrial magnetism. The islands are situated near the important latitude of 38°N. They are removed from all electrical tramways and other sources of disturbance which are harassing the older magnetic observatories; and since their geographical position is intermediate between the old world and the new they are capable of furnishing a valuable link between the records taken in the eastern and the western hemispheres respectively. The Prince, therefore, approached the Portuguese Government with a view of sending Capt. Chaves, director of the meteorological observatory of Ponte Delgada, to Paris to study the arrangements at Parc Saint-Maur. He at the same time undertook to make a preliminary magnetic survey of the archipelago, with a view of fixing upon the most favourable situation for the combined magnetic and meteorological observatory. His suggestion was acted upon, and Capt. Chaves is to enter on his work in April next.

[Albert of Monaco, *Terr. Mag.*, Sept., 1898.]

Wireless Telegraphy Across Paris.—E. Ducretet describes some experiments made in transmitting wireless messages from the Eiffel Tower to the Pantheon. The distance is 2½ miles, and the view across is interfered with by a good many aërial structures. The results obtained were perfectly clear, even in a thick fog. The transmitter was stationed on the third platform of the Eiffel Tower; it consisted of a coil of 25cm. spark-length, worked by a Ducretet motor-interrupter. One of the three spheres of the oscillator was attached to the radiating wire, suspended in space and reaching nearly down to the second platform. Since the wire in the vicinity of the metallic tower acquired a great capacity, the length of sparks in the oscillator was greatly diminished. The receiver, installed on the balcony over the colonnade of the Pantheon, contained a Branly "radio-conductor" and liquid resistances, and a collecting wire 44m. long was connected with it. The signals could be read by their sound with great ease, or could be recorded on the Morse system. In endeavouring to transmit from the Pantheon to the Eiffel Tower no result was obtained, owing to the masses of metal in the latter; but signals could be exchanged between the Pantheon and a mast erected on the roof of the author's laboratory in the Rue Claude Bernard, and projecting 20m. above the surrounding houses.

[Ducretet, *Comptes Rendus*, Nov. 7, 1898.]

Electric Dispersion.—K. F. Löwe has made some experiments to clear up certain points left doubtful after the work of Thomson, Lecher and Drude. It will be remembered that the latter traced a close connection between anomalous electric dispersion and anomalous electric absorption, the former never occurring without the latter. The relation between the numerical values may be represented by

$$a = \tan\frac{\phi}{2}, \text{ where } \tan\phi = \frac{1}{k}\sqrt{(k_\infty - k)(k - k_0)},$$

k being the dielectric constant, and a the corresponding absorption for a given wave-length. Löwe tests the validity of this formula for some esters, organic acids, and glasses. The esters of the fatty acids and benzoic acid show no anomaly either in absorption or dispersion, and so furnish a negative confirmation of Drude's rule. A large number of other esters and alcohols, when examined by means of Nernst's nickel condenser, exhibited what may, by a stretch of generosity, be termed an agreement with Drude's formula. In the glasses, the relation between dispersion and absorption is still less defined. A highly dispersive crown glass showed also the highest absorption. An interesting aspect of the question is the comparison between the absorptions in the solid and the liquid state respectively. This is being pursued by the author.

[Löwe, *Wied. Ann.*, No. 11, 1898.]

Contact Electricity.—A. Coehn recently put forward the statement that the contact electrification between two bodies is determined by their dielectric constants, bodies with a higher dielectric constant being positively charged by contact with a body of a lower dielectric constant. This rule, if universal, furnishes a ready means of determining dielectric constants of substances by their contact electricities with other substances. Even if it is not universal, it will serve the useful purpose of stimulating inquiry. A. Heydweiller has followed up the question by introducing minutely subdivided metals into a narrow tube containing an electrolyte. The electrolyte was made up by mixing water and acetone, or acetone and chloroform in various proportions, thus obtaining liquids with dielectric constants ranging from 5 to 70. The contact electrification between the metal and the liquid was indicated by the motion of the metallic fragments in the tube on passing the current. Thus platinum showed positive electrification in pure chloroform, but negative in all other dielectrics. Gold, tin, cadmium, zinc and aluminium were increasingly positive. So far, then, Coehn's rule was confirmed. But in the alcohols, all metals showed + electrification, and in amyl acetate, with a dielectric constant of 5, they showed − electrification. Perhaps this is due to the solution of positive instead of negative ions, or to some factor not at present taken into account.

Solution of Noble Metals.—M. Margules recently described (see *The Electrician*, Vol. XLI., p. 541) a method of disolving gold and platinum by an electrolytic process. He has since devised a simpler apparatus, consisting of a revolving commutator which alternately sends the current through the cell and short-circuits it. A suitable spacing of the conducting and non-conducting portions of the commutator enables the operator to regulate the ratio of current to short circuit. Another device consists of a hammer interrupter, to which a separate contact piece is attached. At every oscillation, the contact piece produces a short circuit of the cell, or sends a current through the cell in opposition to the first current. Under these circumstances, platinum dissolves at the electrode which is the anode for the stronger current or the greater electric quantity. The behaviour of gold is very different from that of platinum. The latter cannot be dissolved even in hydrochloric acid by means of a constant current, whereas gold is easily dissolved in hydrochloric, strong nitric, and sulphuric acid, under the influence of a constant current. The protection of the noble metals is evidently connected with some phenomenon of polarisation. Eliminate the polarisation, and the nobility disappears.

[Margules, *Wied. Ann.*, No. 11, 1898.]

Selenium Coherers.—Considering that selenium shows a diminution of resistance under the influence of ordinary light, it would not be surprising to find that it was peculiarly effective as a coherer substance. B. Agostini has investigated its properties in this respect in a variety of ways, but so far with negative results. In the interior of a glass tube about 1·5mm. diameter, and between copper electrodes fitting easily in the tube, he placed small fragments of amorphous selenium. By heating the tube to the fusing point of selenium and lightly compressing the substance, he obtained a solid cylinder of selenium in the centre of the tube, which adhered to the electrodes. Sixteen such tubelets were prepared and tied in a sheaf, and the whole brought into a thermostat, which allowed of the maintenance of any temperature from 195deg. downwards. While the resistance in the dark was 111,000 ohms, and under the influence of light 62,000 ohms, the resistance increased, under the influence of electric waves from a Righi short-wave oscillator provided with a parabolic mirror, by about 1,000 ohms. Testing with a Lippmann capillary electrometer instead of a galvanometer, a slightly larger increase, about 1·6 per cent., was obtained. In other cases there was a diminution of about the same amount. The changes are within the limits of experimental error, and are probably accounted for by temperature variations, leaving nothing for a coherer action proper.

[Agostini, *Nuovo Cimento*, August.]

ELECTROMAGNETIC THEORY.—CX.*

BY OLIVER HEAVISIDE.

(Continued from page 786.)

§ 442. The product of ϵ^x and ϵ^{-x} is 1. If, then, the product of the same when generalised came to 2 or to x, we could be sure there was something wrong. But we need not expect that the product should reduce to 1 in a plain manner. The product, say Q, of the generalised series for ϵ^x and $\epsilon^{-x}\cos r\pi$ makes the power series

$$Q = \ldots + x^{2r}\phi(r) - x^{2r+2}\phi(r+1) + x^{2r+4}\phi(r+2) - \ldots, \quad (189)$$

where $$\phi(r) = \frac{1}{\lfloor r \rfloor^2}\left\{1 - \frac{2r}{r+1}\left(1 - \frac{r-1}{r+2}\left(1 - \frac{r-2}{r+3}\left(1 - \ldots\right\}, \quad (190)$$

which may be transformed to

$$\phi(r) = \frac{1}{\lfloor r \rfloor^2}\frac{(1-r)(2-r)(3-r)\ldots}{(1+r)(2+r)(3+r)\ldots} = \frac{1}{\lfloor r \rfloor^2}\frac{(1-1)^r}{(1+1)^r}. \quad (191)$$

So $\phi(r)$ is 0 when r is +, and is ∞ when r is −, unless integral. Q is 1 when r is 0, and is −1 when r is 1, and so on. But when r is fractional, Q assumes the indefinite form of a succession of infinities, not plainly reducible to $\cos r\pi$.

Write (140) thus,

$$w = \Sigma\frac{x^r}{\lfloor r}\frac{1}{\cos r\pi}. \quad (192)$$

When x is +, w is ϵ^{-x}. Differentiate to r, then

$$w' = \Sigma\frac{x^r}{\lfloor r}\frac{1}{\cos r\pi}\Big(\log x + \mathrm{G}(r) + \pi\tan r\pi\Big). \quad (193)$$

This is zero when x is +. Compare with u and u' before considered, representing ϵ^x and 0. The $r=0$ case of (193) is

$$w' = \epsilon^{-x}(\log x + \mathrm{C}) - \left(\frac{1}{x} + \frac{1}{x^2} + \frac{2}{x^3} + \ldots\right) + \left(x - \frac{x^2}{\lfloor 2}(1+\tfrac{1}{2}) + \ldots\right). \quad (196)$$

Compare with (93) above. That, by (97), makes a rapid approximation to the value of C. The present formula does not, for the same figures are differently arranged, which makes the l.c.t. large.

Since u satisfies $(\Delta - 1)u = 0$, it must be $A\epsilon^x$, where A is a function of r. This being 1 when x is +, if it is different when x is −, it is made a function of x. So there seems to be an irreconciliabity, requiring some modification of ideas, perhaps. But u', u'', &c., also satisfy the characteristic, and so does

$$X = u + A_1u' + A_2u'' + A_3u''' + \ldots. \quad (195)$$

Moreover, the value of X is simply u, or ϵ^x, when x is positive. Similarly, the characteristic $(\Delta + 1)w = 0$, is satisfied by

$$Y = w + B_1w' + B_2w'' + B_3w''' + \ldots, \quad (196)$$

and the value of Y is w, or ϵ^{-x}, when x is positive. When x is negative, or complex, we do not know what they are. As the A's and B's may be various, we may have transitions from X to Y. Here is one. Say

$$\epsilon^{-x} = w + Bw'. \quad (197)$$

Put $x = -z = zi^2$. Then we get

$$\epsilon^z = \Sigma\frac{z^r}{\lfloor r}(1 + i\tan r\pi)$$

$$B\Sigma\frac{z^r}{\lfloor r}(1 + i\tan r\pi)\,(\log z + \mathrm{G}(r) + i\pi + \pi\tan r\pi), \quad (198)$$

which splits into equations which may be written

$$\epsilon^z = u + Bu', \quad (199)$$

$$0 = \left(1 + B\frac{d}{dr}\right)\Sigma\frac{z^r}{\lfloor r}\tan r\pi. \quad (200)$$

Whether this be a proper transformation or not, equations (197) and (199) are consistent. For with z positive and therefore x negative, both equations are true, if (197) is true for x negative as well as positive. But further investigation is reserved.

§ 443. We may derive a power series for the logarithm of x from the binomial theorem

$$\frac{(1+x)^n}{\lfloor n} = \Sigma\frac{x^r}{\lfloor r \lfloor n-r}. \quad (201)$$

Differentiate to r. Then

$$-\log x = \Sigma\frac{x^r}{\lfloor r \lfloor n-r}\Big(\mathrm{G}(r) - \mathrm{G}(n-r)\Big). \quad (202)$$

In the simpler case of $n=0$ this is

$$-\log x = \Sigma\, x^r\frac{d}{dr}\frac{\sin r\pi}{r\pi} = \Sigma\frac{x^r}{r}\left(\cos r\pi - \frac{\sin r\pi}{r\pi}\right). \quad (203)$$

When $r=0$ this makes

$$-\log x = \Sigma\frac{x^r}{r}\cos r\pi, \quad (204)$$

without the zeroth term for $r=0$. That is,

$$\log x = x - x^{-1} - \tfrac{1}{2}(x^2 - x^{-2}) + \tfrac{1}{3}(x^3 - x^{-3}) - \ldots, \quad (205)$$

that is, the sum of the logarithms of $1+x$ and $(1+x^{-1})^{-1}$ according to the common formula.

In the case $r = \frac{1}{2}$,

$$\log x = \frac{1}{\pi}\Sigma\frac{x^r}{r^2}\sin r\pi; \quad (206)$$

* This series of Articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

or, putting $x=y^2$,

$$\frac{\pi}{2}\log y = y - y^{-1} - \tfrac{1}{3}(y^3 - y^{-3}) + \tfrac{1}{2\,5}(y^5 - y^{-5}) - \dots . \quad (207)$$

The two formulæ (205) and (207) both lead to $\log i = \frac{1}{2}i\pi$.

Differentiating (204) to x, we get

$$-\frac{1}{x} = \Sigma\, x^{r-1}\left(\cos r\pi - \frac{\sin r\pi}{r\pi}\right), \quad (208)$$

Multiply by x and use the result (43); we then reduce to

$$0 = \Sigma\, x^r \cos r\pi. \quad (209)$$

The $r=0$ case is $\quad 0 = (1+x)^{-1} - x^{-1}(1+x^{-1})^{-1}. \quad (210)$

Also (208) seems to give a power series for x^{-1}. But it is only a particular form of (209).

Differentiating (209) to x gives

$$0 = \Sigma\, x^r \sin r\pi. \quad (211)$$

Equation (206) may be used numerically. I have also verified that the more general formula (203) goes when $r=\frac{1}{4}$, the error vanishing when $x=1$.

Put $y=xi$ in (207). We get the well-known

$$\frac{\pi}{4}z = \sin z - \tfrac{1}{3}\sin 3z + \tfrac{1}{2\,5}\sin 5z - \dots . \quad (212)$$

Again, putting $x=\epsilon^{\pi i}$ in (203) we get

$$-z = \Sigma\,\frac{x^r}{\lfloor r}\left(\cos r\pi - \frac{\sin r\pi}{r\pi}\right), \quad (213)$$

which, when $r=0$, makes the well-known

$$\tfrac{1}{2}z = \sin z - \tfrac{1}{2}\sin 2z + \tfrac{1}{3}\sin 3z - \dots . \quad (214)$$

Although these substitutions of imaginary for real values are successful in the special cases chosen, they are only experimental, for the *theory* of generalised functions is *in nubibus* as yet.

§ 444. In § 433 this formula, equation (80), was arrived at from the binomial theorem *viâ* the logarithmic function :—

$$(1+x)^{-1} = \Sigma\, x^r g(r) g'(-r-1). \quad (215)$$

Put Δ^{-1} for x and algebrise with unit operand; then we get

$$\epsilon^{-x} \;||\; \Sigma\, x^r [g(r)]^2 g'(-r-1). \quad (216)$$

Do the same again, and we get

$$J_0(x) \;||\; \Sigma\,\frac{(\frac{1}{2}x)^{2r}}{(\lfloor r)^2}\, g'(-r-1). \quad (217)$$

Here || is used to indicate a possible or apparent equivalence; it may not be one, or it may. The method is a very speedy way of generating new formulæ, and sometimes gives true equivalences, at other times only partial ones.

Now (217) is easily seen to be incorrect. What about (216), then? And is not (215) to be suspected? It may be readily tested. Multiply by $1+x$. The result is

$$1 = \Sigma\,\frac{x^r}{\lfloor r}\Big(g'(-r-1) + r g'(-r)\Big), \quad (218)$$

which is identically the same as

$$1 = \Sigma\,\frac{x^r}{\lfloor r\,\lfloor -r} = \Sigma\, x^r \frac{\sin r\pi}{r\pi}, \quad (219)$$

which formula was obtained before equation (43). It asserts that $\epsilon^{\Delta}1 = 1$, and often turns up as a connecting formula. It satisfies the characteristic

$$(1+x)\Delta u = 0, \quad (220)$$

i.e., $\Delta u = 0$, therefore u is constant as regards x. Numerically considered, however, it can only be used when x is near to 1. When $x=1$, we have such series as

$$(r=\tfrac{1}{2}) \quad \frac{\pi}{4} = 1 - \tfrac{1}{3} + \tfrac{1}{5} - \tfrac{1}{7} + \dots, \quad (221)$$

$$(r=\tfrac{1}{4}) \quad \frac{\pi}{4}\sqrt{2} = 1 + \tfrac{2}{1\,5} - \tfrac{2}{6\,3} + \tfrac{2}{1\,4\,3} - \tfrac{2}{2\,8\,3} + \dots . \quad (222)$$

There is no reason, so far, to doubt (215).

Passing to (216), see on what the satisfaction of the characteristic of ϵ^{-x} by the right member depends. The result is

$$0 \;||\; \frac{d}{dx}\Sigma\,\frac{x^r}{\lfloor r}\,\frac{\sin r\pi}{r\pi}. \quad (223)$$

If the || can be replaced by $=$, then (216) will go. Integrating to x,

$$1 \;||\; \Sigma\,\frac{x^r}{\lfloor r}\,\frac{\sin r\pi}{r\pi} = v, \text{ say}, \quad (224)$$

because it is 1 for a special case, though the left side might be a function of r. On numerical testing, v seems to be 1 very closely. Thus take $r=\frac{1}{2}$; then $x=5$ makes $v=0{\cdot}9993$ by a long sum of about 20 terms. But this x may not be small enough to show an auxiliary satellitic function, if it exists. Now $x=2$ makes $v=1{\cdot}009$ with, and $1{\cdot}0009$ without the l.c.t. Again with $x=1$, I get $1{\cdot}063$ with and $1{\cdot}0093$ without the l.c.t. The error rule seems to fail here; for example, the last result is nearly 1 per cent. more than the size of the l.c.t. would allow. However, passing to $x=\frac{1}{2}$, the rule is satisfied, and also with $x=\frac{1}{4}$, although now the error itself has become large.

Testing (223) in the same way, with the same values of r and x, the value 0 comes out right (within the error limits) all through. Also with $x=3$. Unless, therefore, errors in calculation are involved, it would seem that the error rule, by which the l.c.t. finds the error, is not a complete rule.

Try with $r=\frac{1}{4}$. Here

$$g^2(\tfrac{1}{4}) = 1{\cdot}21690, \qquad g(\tfrac{1}{4}) = 1{\cdot}10313,$$

by the formula (188) above with $n=0$, and $r=\frac{1}{4}$. Applying these to (224), with $x=2,\ 1,\ \frac{1}{2},\ \frac{1}{4}$, the results are a little less than 1 throughout, and within the error limits. We can say that v is certainly closely equal to 1 save when x is small, when the l.c.t. is too big for any certain conclusion.

But that (224) is not a real equivalence is to be seen by differentiating it to r. Thus

$$v' = v\log x + \Sigma\,\frac{x^r}{\lfloor r}\mathrm{G}(r)\frac{\sin r\pi}{r\pi} + \Sigma\,\frac{x^r}{\lfloor r}\,\frac{\cos r\pi - (r\pi)^{-1}\sin r\pi}{r}. \quad (225)$$

Where $r=0$, this reduces to

$$v' = \log x + \mathrm{C} - \left\{x - \tfrac{1}{2}\frac{x^2}{\lfloor 2} + \tfrac{1}{3}\frac{x^3}{\lfloor 3} - \dots\right\} \quad (226)$$

$$= -\epsilon^{-x}\left\{\frac{1}{x} - \frac{1}{x^2} + \frac{\lfloor 2}{x^3} - \frac{\lfloor 3}{x^4} + \dots\right\}. \quad (227)$$

Here v' is zero only when $x=\infty$. So $v \;||\; 1$ is only an apparent equivalence. The characteristic of v is

$$(\Delta+1)x\Delta v = 0, \quad (228)$$

$$\therefore\ v = a\int\frac{\epsilon^{-x}}{x}dx = \mathrm{A} + a\left[\log x + \mathrm{C} - \left(x - \tfrac{1}{2}\frac{x^2}{\lfloor 2} + \dots\right)\right], \quad (229)$$

where C, or G(0), is brought in to make $[\dots]=0$ when $x=\infty$. A and a are functions of r. From the preceding A is 1, and a is periodic. To harmonise with (226), we may write

$$v = 1 - \frac{\sin 2\pi r}{2\pi}\left[\left(x - \tfrac{1}{2}\frac{x^2}{\lfloor 2} + \dots\right) - (\log x + \mathrm{C})\right]. \quad (230)$$

So $v=1$ when r is integral and midway between, and is nearly 1 for any r, if x is over 1.

The sine function thus reached may also be utilised thus. Equation (228), by (224), means the same as

$$\Sigma\,\frac{x^r}{\lfloor r}\,\frac{\sin r\pi}{\pi} = a\epsilon^{-x}. \quad (231)$$

Divide by $\pi^{-1}\sin r\pi\cos r\pi$. Then

$$\Sigma\,\frac{x^r}{\lfloor r}\,\frac{1}{r\cos r\pi} = \frac{2\pi a}{\sin 2\pi r}\epsilon^{-x} = \epsilon^{-x}. \quad (232)$$

Comparing with (140), we see that the present investigation leads to the generalised ϵ^{-x} formula which harmonised the Bessel functions. Numerically tested, the formula (230) goes with $x=1,\ \frac{1}{2},\ \frac{1}{4}$.

§ 445. Passing now to the generalised formula

$$\mathrm{W} = \epsilon^{x}\pi^{\frac{1}{2}}\Sigma\,\frac{(\frac{1}{2}x)^r}{(\lfloor r)^2\,\lfloor -\frac{1}{2}-r}, \quad (233)$$

before obtained, equation (53). First test that W satisfies the characteristic of $I_0(x)$ identically. It therefore involves I_0 or

Digitized by Google

K_0, or both. But can K_0 come in at all? W is the convergent I_0 when $r=0$, and is the equivalent divergent $\frac{1}{2}H_0$ when $r=\frac{1}{2}$. Now when r is arbitrary, we may, by the use of the corresponding generalised ϵ^x series, reduce W to an integral power series. But the solution of the characteristic equation of I_0 in an integral power series was shown to split into two series (even and odd terms), which satisfy the characteristic separately, and are, moreover, equivalent. This strongly suggests that W does not involve K_0 at all, but is $I_0(x)$ a periodic function of r, which is 1 when r is 0 and $\frac{1}{2}$. Or, in terms of the even and odd series, $W=aA+bB$, where A is $I_0(x)$ and B is the equivalent series in odd powers as in (44), (45). I tried to test this numerically, to fix a and b. But the series to find a and b are divergent with wide error limits, so it was no good this way.

In order to detect the satellite, take $r=\frac{1}{4}$. The result (numerically) is that W is sensibly I_0 when x is big, but falls slightly below I_0 as x is reduced to 1, $\frac{3}{4}$, $\frac{1}{2}$. Then take $r=-\frac{1}{4}$, and test. As x is reduced W now *rises* slightly *above* I_0. This difference, + or − as the case may be, increases as x decreases.

The form of W is therefore probably I_0-cK_0, as in the case of U before, and c has to be found. Finding the result of reducing W to an integral power series difficult to manage, try another way. Use the ordinary ϵ^x series in (233). The result is then

$$W=\Sigma\, y^{\frac{1}{4}r}\phi(r), \tag{234}$$

where $y=\frac{1}{4}x^2$ and the step of r is 1, whilst

$$\phi(r)=2^r\pi^{\frac{1}{2}}\left\{\frac{2^r}{(\lfloor r)^2\lfloor -r-\frac{1}{2}\rfloor 0}+\frac{2^{r-1}}{(\lfloor r-1)^2\,-r+\frac{1}{2}\rfloor 1}+\ldots\right\}. \tag{235}$$

This is a stopping series, and is convergent, so can be closely calculated. With r integral, we get $I_0(x)$. With $r=$ integer $+\frac{1}{2}$, we get a result reducible to

$$W=\tfrac{1}{2}(U_{\frac{1}{2}}+U_{-\frac{1}{2}})=\tfrac{1}{2}H_0(x). \tag{236}$$

In general, (234) makes

$$W_r=AU_{\frac{1}{2}r}+BU_{-\frac{1}{2}r}, \tag{237}$$

where A and B are functions of r to be found. Understand that U is the previous $U_{n,r}$ function, with $n=0$, as in § 439.

In the case of $r=\frac{1}{4}$ the result is

$$W_{\frac{1}{4}}=0{\cdot}8525\,U_{\frac{1}{4}}+0{\cdot}1460\,U_{-\frac{3}{4}}, \tag{238}$$

where

$$U_r=\tfrac{1}{2}(H_0-\sin 2\pi r\,.\,K_0)(x). \tag{239}$$

This makes

$$W_{\frac{1}{4}}=\tfrac{1}{2}H_0-\tfrac{1}{4}K_0, \tag{240}$$

very closely. Note that (238) is an identity, subject to the use of the ordinary ϵ^x series; whilst (240) is a conveniently substituted equivalence.

The general identical formula corresponding to (238) is

$$W_r=U_{\frac{1}{4}r}\cos^2\tfrac{1}{2}\pi r-U_{-\frac{1}{4}r}\sin^2\tfrac{1}{2}\pi r. \tag{241}$$

I have verified it numerically for eight values of r, namely, 0, $\frac{1}{8}$, $\frac{1}{4}$, &c., up to $\frac{7}{8}$. Using (239) in it, the result is

$$W_r=\tfrac{1}{2}(H_0-\tfrac{1}{2}\sin 2\pi r\,K_0)(x). \tag{242}$$

The satellite for W_r has only half the mass of that for U_r. The value of $\phi(r)$ in (235) is

$$\phi(r)=[g(\tfrac{1}{2}r)\cos\tfrac{1}{2}\pi r]^2. \tag{243}$$

The reduction of W_r (involving K_0) to an integral power series, before referred to, implies that the series, which satisfies the characteristic as a whole, does not do so in two independent ways. The expansion (137) above illustrates this. Both the even and the odd powers have to be included to satisfy the characteristic. The characteristic is

$$(DyD-1)K_0=0, \tag{244}$$

if $D=d/dy$, and this is satisfied because the odd power series when operated upon by $(DyD-1)$ gives $-D\Sigma y^r[g(r)]^2$, with $r=\frac{1}{2}$, whilst the even power series gives + (the same), with $r=0$. On addition, therefore, (244) is obeyed.

Of course, when W is expanded in the form (234), it does split into two series, as in (241), which separately satisfy the characteristic. But it seems that this is the exceptional case, and that there is no double satisfaction when the generalised ϵ^x is used.

The satellitic terms in both cases, U and W, become very important when x nears the origin. But then the series cannot be used for calculation, on account of the largeness of the possible error. So, practically, both U and W are apparently I_0; and the small correction may be eliminated by using two values of r; thus,

$$I_0(x)=\tfrac{1}{2}(U_r+U_{-r})=\tfrac{1}{2}(W_r+W_{-r}). \tag{245}$$

§ 446. If the characteristic be of the third order, its three solutions will be all included in one generalised solution, and will be separable therefrom by giving special values to r. If $r=0$ makes the primary, the other two solutions are likely to enter satellitically in the general solution. Similar remarks may apply to higher orders, but there is some work to be done to investigate fully.

The apparent equivalence

$$I_0(x)\,\|\,\Sigma\frac{y^r}{(\lfloor r)^2} \tag{246}$$

arises from $\epsilon^{D^{-1}}1=I_0(x)$; where $D=d/dy$, and $y=\frac{1}{4}x^2$. If we change y to Δ^{-1}, and algebrise again, with unit operand, we obtain

$$1+y+\frac{y^2}{(\lfloor 2)^3}+\frac{y^3}{(\lfloor 3)^3}+\ldots\,\|\,\Sigma\frac{y^r}{(r^3)}=w_r. \tag{247}$$

The characteristic is now

$$(DyDyD-1)w=0. \tag{248}$$

It has three independent solutions. One of them, w_0, with $r=0$, is the left member of (247). All three are included in w_r. Nevertheless, $w_0\,\|\,w_r$ is an apparent equivalence.

Taking $r=\frac{1}{2}$, the original equation (246) is a true equivalence, but (247) is not. (Besides $r=0$, $\frac{1}{3}$ and $\frac{2}{3}$ are probably the important values.) For w_0 is a little greater than $w_{\frac{1}{2}}$ when $y=1$, the ratio being about 0·967. Increasing y improves the equivalence; $y=3$ and above making $w_{\frac{1}{2}}$ a little greater than w_0, the ratio being 1·001 when $y=8$.

Going a step further in the same way to the fourth order, say

$$w_r=\Sigma\frac{y^r}{(\lfloor r)^4}, \tag{249}$$

and comparing w_0 with $w_{\frac{1}{2}}$, the numerical equivalence is so close as to make one think it may be an exact one here specially. Still $w_{\frac{1}{2}}$ is the smaller when $y=1$, though a trifle greater from $y=2$ up to 9.

Passing on to

$$w_r\,\|\,\Sigma\frac{y^r}{(r)^8}, \tag{250}$$

there is a falling off in agreement; for as y increases from 1 to 36, the ratio $w_{\frac{1}{2}}/w_0$ falls continuously from 1·37 to 0·907.

One more case to show further falling off. Let

$$w_r\,\|\,\Sigma\frac{y^r}{(\lfloor r)^{16}}. \tag{251}$$

The peculiarity here (and in the last case less markedly) is the very large ratio, namely 2^{16}, of the coefficient of $y^{\frac{1}{2}}$ to that of $y^{-\frac{1}{2}}$ in the series $w_{\frac{1}{2}}$, whereas the succeeding ratios are quite small. This may affect the determination of the error in a complete rule. Anyhow the tendency shown in the last case is now more marked, for $w_{\frac{1}{2}}/w_0$ falls from 3·3 to 0·75 as y goes from 1 to 100. There is equality at about 49.

The above series of formulæ are such good apparent equivalences at the beginning, though so bad later on, that it is suggested to examine the formulæ which arise from the equivalence $1=\Sigma\, x^r(r\pi)^{-1}\sin r\pi$, equation (219), in a similar way. The first one, turning x to Δ, and algebrising, is the apparent equivalence (224) above, shown to be excellent. But others, of the types

$$w_r=\Sigma\, x^r\left(\frac{\sin r\pi}{r\pi}\right)^n, \qquad w_r=\Sigma\frac{x_r}{\lfloor r}\left(\frac{\sin r\pi}{r\pi}\right)^n, \tag{252}$$

with n integral and greater than 1, are found by a cursory examination not to furnish apparent equivalences, at least as regards $r=0$ and $\frac{1}{2}$.

(To be continued.)

[Errata. § 438: Between (133) and (134) *for* $\frac{1}{000}$ *read* $\frac{1}{1000}$. § 441: In equations (184) and (185), *for* cos *read* sin; and in equation (186) *for* $n\frac{1}{2}$ *read* $\pi^{\frac{1}{2}}$.]

THE LANGDON-DAVIES MOTOR WORKS.

We have had an opportunity of visiting the works of the Langdon-Davies Electric Motor Co., in Southwark-street, and the activity that prevails there should quite dispel the idea that an alternating-current supply station may hope in vain for a motor load unless it is prepared to lay down a subsidiary continuous-current network. The two disadvantages of an alternate current motor, viz., its inability to start under a heavy load, and the power-factor, are counterbalanced to some extent in the Langdon-Davies motor by its absence of brushes. The power-factor is a difficulty which cannot be got over; with regard to the first defect, however, the makers rightly point out that a gas-engine is in a worse plight, being not even self-starting. This article is not intended, however, to consider critically and at length the merits and demerits of single and alternating currents from the supply engineers' or consumers' point of view, and we will confine ourselves to a description of the motor itself, and of the works where it is constructed.

Two years ago* we entered fully into the theoretical considerations underlying the design of this machine, and it is unnecessary to repeat them now. It will suffice to recall the fact that the rotating part of the motor is merely a number of short-circuited coils wound on an iron core carried on the motor shaft, while the position and proportions of the stator coils are such as to produce a rotating field, a starting winding being added which is switched off as soon as the motor has attained its full speed. From Fig. 2 a clear idea of the mechanical construction of the motor can be obtained. The stator coils are wound in slots in the laminated core held in the cast-iron carcase of the motor. They are insulated from the iron by a thin lining of vulcanised fibre being given to the slots, and the various windings are insulated from one another by "presspan," or by a thin sheet of other insulating material. The bearings are a particularly noticeable feature; they are of cast iron, no bushes being used within the brackets. The ring lubrication used is clearly seen in the figure; slight grooves are cut in the bearing, so that the oil is kept continuously circulating along the shaft and back to the oil bath. The rotor coils are embedded in slots milled in the rotor core, which is held by a gun-metal spider in the customary manner. These slots, it may be mentioned, are not parallel to the shaft, but slant with what may be called a one-bar pitch; that is to say, the imaginary line joining the front end of one slot with the back end of the adjacent one is parallel to the spindle. An ingenious method is employed to fit the stator without the necessity of machining the interior of its core. The stampings are clamped up in a "jig," which has an axle just as the motor spindle, and this is held in position in the stator frame by the bearing brackets which have already been fitted. A cast-iron ring is then put on, clamping the stampings in position, and this is fixed to the carcase, and the

jig then removed, leaving the stampings clamped concentric with the motor shaft. Before either the rotor or stator are wound, the former is put in position and run for a considerable time to test the bearings. The air-gap is in the neighbourhood of $\frac{1}{32}$in. Fig. 1 is a view of a 25 H.P. motor, all sizes above 9 H.P. being built on this pattern. The frame of this motor is supported in such a way that the whole machine may be moved bodily with the loosening of only a single screw, for the purpose of tightening the belt.

FIG. 6.—Testing a Motor.

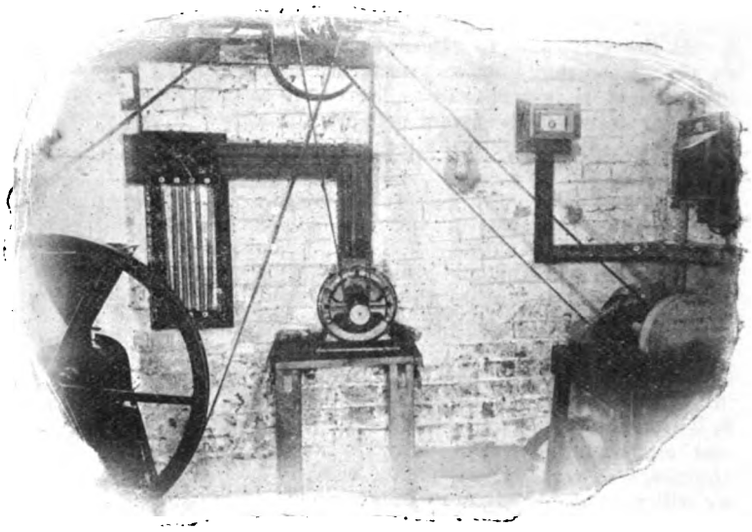

FIG. 7.—Coffee Grinder and Sausage Machine driven by Langdon-Davies Motor.

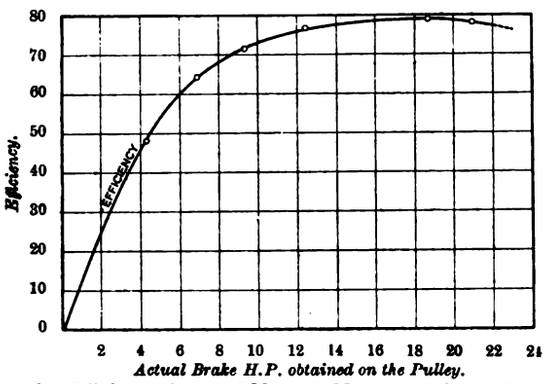

FIG. 8.—Efficiency Curve of 20 B.H.P. Motor, tested at 100 volts and 87 ∽ per sec.

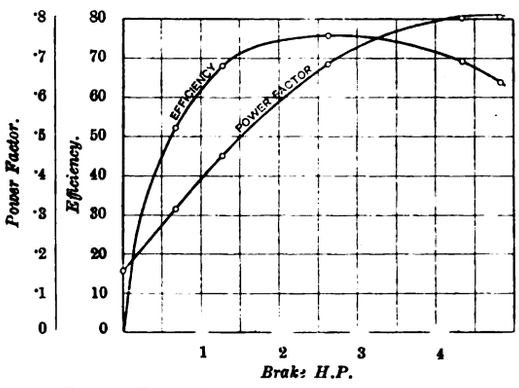

FIG 9.—Power Factor and Efficiency of 4 B.H.P. Motor.

The works of the Langdon-Davies Electric Motor Co. are, we believe, the only ones in this country which are exclusively devoted to the manufacture of motors, their switches and resistances. All the machinery, with the exception, we believe, of one foot-lathe, is driven by Langdon-Davies motors, supplied from the London Electric Supply Corporation's mains at 100 volts pressure and 88 ∽ per second frequency. The premises are also lit electrically, and there is a lift driven by a Langdon-Davies motor. A separate transformer and meter is provided for each of these three purposes. The lift is intended to convey material weighing up to one ton. It is driven by an 8 H.P. motor, and moves at about 40ft. per minute. The motor is connected to the winding drum by belt gearing through a countershaft, the use of an ordinary and a crossed belt providing for the changes in direction. As the lift is not being used continuously the motor is normally at rest, and has first to be run up to speed on a loose pulley.

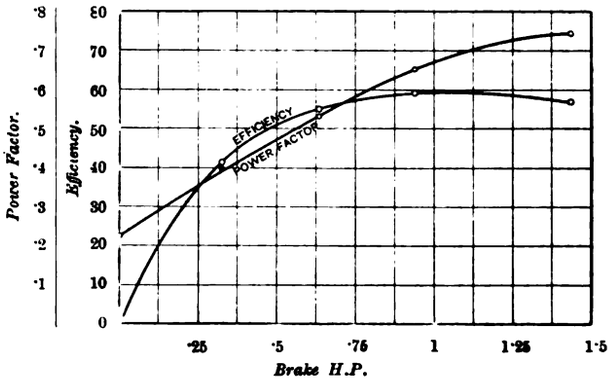

FIG. 10.—Power Factor and Efficiency of 1 B.H.P. Motor.

The machine shop is in the basement of the building, and is driven by a 3 H.P. and a 6 H.P. motor. The former (Fig. 3) is fixed just under the ceiling, and suffices for a planing machine and a 12in. lathe; it runs at 2,400 revolutions per minute and

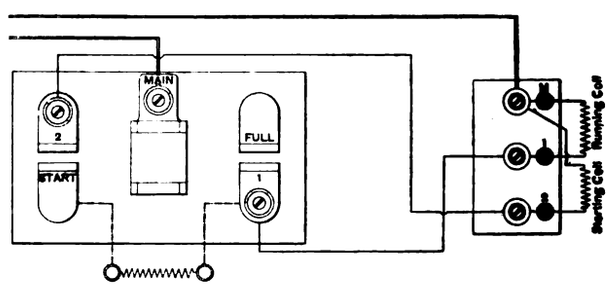

FIG. 11.—Connections of Starting Switch.

Digitized by Google

drives the countershaft at about 150. When we inspected the works the planing machine was working on a moderately heavy casting, and in spite of the cut being of a fair depth it was interesting to note the enormous rise of the current through the ammeter in the motor circuit during the faster back stroke. It may here be mentioned that every motor on the works is provided with an ammeter so that the load may be observed at any time. The 6 H.P. motor (Fig. 4) is placed on the floor, and drives eight lathes, two milling and two drilling machines. The ground floor of the building is devoted to the offices of the Company, and the other floors to the winding, fitting, testing and pattern shops. All are light and airy, and well provided with electric light. Our illustrations give an idea of the arrangement of some of the shops. One of the machines not shown in them is a mangle adapted for the purpose of lacquering the core-discs; it is said to do this better and quicker than a paint brush. A 3 B.H.P. motor in the pattern shop does its fair share of work, driving two lathes, a saw and a grindstone. A simple yet convenient switchboard is provided in the testing shop, being fitted with ammeters, voltmeters and wattmeters to measure what is supplied to the motors, and a Soames absorption dynamometer (see *The Electrician*, Vol. XL., p. 524) is used to measure the output.

The curves in Figs. 8, 9 and 10 show the efficiencies and power factors of three different sizes of motors, and Fig. 11 indicates the connections of the starting switch. The switch is of the change-over type, and is first put to the left, connecting the starting coil directly to the mains and the running coil to the mains through a resistance. As soon as the motor has run up to speed the switch is put over on to the right-hand contact, which connects the running coil directly to the mains. The motors are always fitted with double-width pulleys, so that they may be started on a loose pulley on the counter-shaft and the belt thrown over to the fast pulley at full speed. The resistance of the starting coil and the added resistance to the running coil, however, prevent more than the full-load current from flowing at starting.

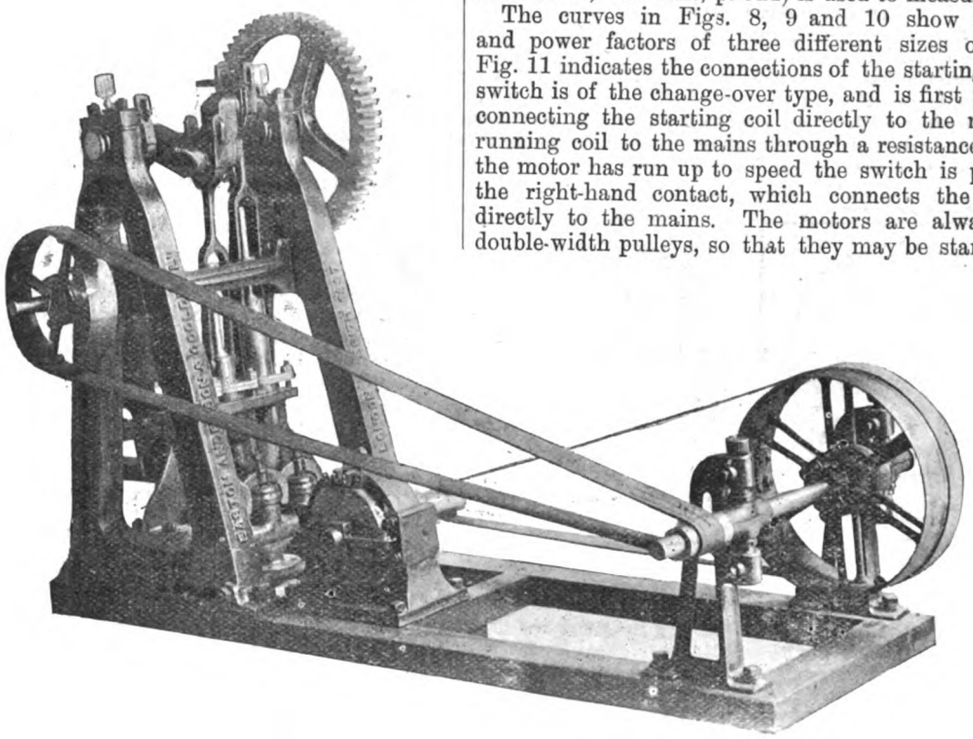

FIG. 10.—Direct-Acting Pump driven by Langdon-Davies Motor.

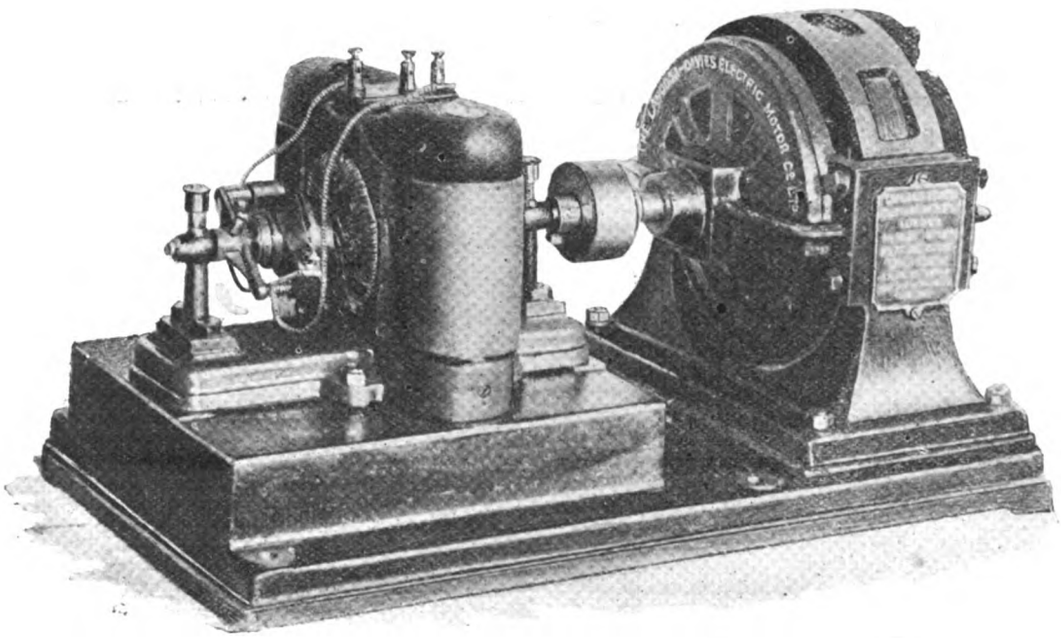

FIG. 11.—Dynamo Coupled to Langdon-Davies Motor.

In conclusion, we may notice one fact that speaks volumes for the efficiency of the methods employed at the Langdon-Davies works. The prices of the motors are now comparable with those of continuous-current motors.

ROTATORY CONVERTERS.*

BY PROF. SILVANUS P. THOMPSON.

(Concluded from page 165.)

Amongst continental firms Messrs. Alioth, of Basle, have been prominent in the application in the industry of rotatory converters, which they designate as *commutatrices*. Mr. R. B. Ritter, one of their engineers, has kindly furnished many particulars of these machines and of their application. Articles by him on this subject have appeared in *L'Industrie Électrique* for 1896. He points out that in the application of these machines to charge accumulators from an alternating-current supply means are necessary for changing the voltage as between charge and discharge. There are several ways of meeting this need—by the use

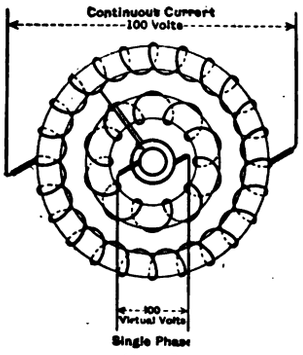

FIG. 9.

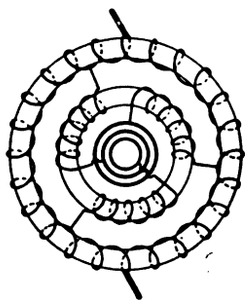

FIG. 10.

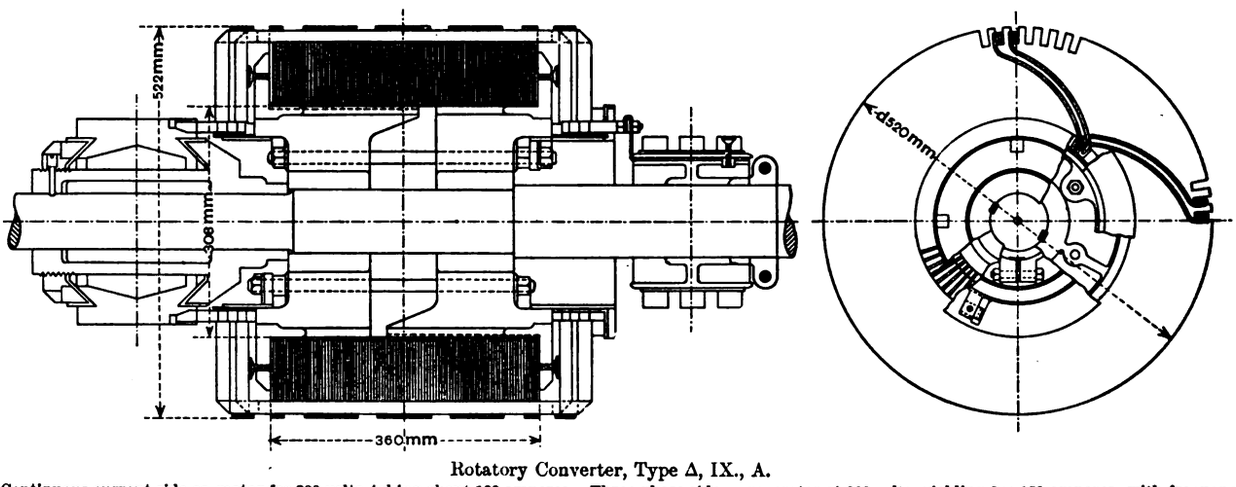
of choking coils, or of auto-transformers of variable ratio in the alternating side of the circuit, or by throwing in or out of circuit of a supplementary armature. The solution preferred by M. Ritter is the latter, a small auxiliary continuous-current machine in series with the continuous-current side being either mounted on the same shaft or driven by a pulley from it. The desired variations of voltage can be obtained by varying the excitation of the separate field-magnet provided for this auxiliary machine. A large 100-kilowatt two-phase converter, constructed by Messrs. Alioth for Geneva, is described in *The Electrician* of January 8, 1897, with sectional drawings. This is a 14-pole ring armature machine, having an armature 1 metre in diameter, running at 385 revolutions per minute. As it is designed to supply continuous currents to a three-wire distribution, it is wound with two independent converter windings, each capable of supplying 450 amperes at 110 volts; and is furnished with four slip rings, and with a commutator at each end. It has an efficiency of 90 per cent.

The problem of changing into convenient simple ratios the awkward percentage numbers which subsist between the voltages at the two sides of a converter has engaged the attention of several engineers. Mr. Heldt has described† an ingenious method of obtaining any desired ratio by the device of including on the alternating-current side additional windings between the slip-rings and the points where these rings are connected up to the armature winding proper. Fig. 9 illustrates the case of a single-phase converter. Here auxiliary windings (in two parallel circuits) are joined in so as to bring up the 70·7 volts on the alternating side to 100 volts, so as to make the voltages alike at both sides of the machine. To adapt this suggestion to the case of a three-phase converter, three sets of auxiliary windings must be intercalated between the three slip rings and the points of connection to the ring winding; these auxiliary windings being chosen, as to number and position, so as to add the desired supplementary voltage. It will be seen that this is equivalent to using a mixed star and delta winding; the delta part being that which alone constitutes the true converter winding. It is uniformly distributed around the core, and is symmetrically connected to the commutator.

Another solution of the problem, of more limited application, lies in so altering the distribution or concentration of the magnetic field at the poles as to change the irregular ratios into more regular ones. It was pointed out above that any concentration of the field will alter the conversion ratio. For example, the ratio in the case of the three-phase converter with sine distribution being 61·23 per cent., if the poles are narrowed a little, this may be raised to 66·6 per cent., so that a machine which is a 300-volt machine on the continuous-current side will be a 200-volt machine on the three-phase side. An example of this is afforded by a four-pole 55-kilowatt converter constructed by the Oerlikon Company, the description of which has been kindly furnished by Dr. Behn-Eschenburg. Drawings of this machine are given in Figs. 11 and 12. It was designed to receive continuous current at 300 volts, and to run at 600 revolutions per minute. Its armature is a two-circuit multipolar drum 522mm. in diameter, 360mm. long, having 117 slots and two conductors per slot. It has four sets of carbon brushes, set at zero lead. It runs quite sparklessly at all loads. As originally constructed, the poles were furnished with pole-pieces (as shown) each of about 72deg. span, therefore having a breadth about 80 per cent. of the pole-pitch; the chord across the tips being 335mm. So shaped, the coefficient of conversion was found to be 57·7 per cent., as against the 61·23 per cent. if sine distribution had been present. When supplied at 300 volts on the continuous-current side, its open-circuit three-phase voltage was only 173 volts. The pole-tips were then cut away, as shown in Fig. 12, so that the arc of pole-span was reduced to a little under 50deg.; the chord across the tips being now 228mm., and the pole-breadth being 54 per cent. of the pole-pitch. This had the effect desired of bringing the conversion ratio up to 66·6, the open-circuit three-phase voltage being now 200. The ratio of conversion was constant within 2 per cent. at all loads. Fig. 13 gives a plot of the performance of the machine under different excitations. It will be seen that the ratio of the ordinates is approximately that of 3 : 2. Two other points plotted show the demagnetising reaction due to wattless currents. They affect, of course, the speed and heating of the machine, but practically have no influence upon its ratio of conversion when the excitation of the field magnets is normal. In its original shape, when operated as continuous-current motor at 300 volts with an excitation of 2·1 amperes, without load on the three-phase side, it ran at about 470 revolutions per minute. When loaded so as to give out 153 amperes per phase on an inductionless circuit the speed fell, in consequence of reactions, to 440 revolutions per minute. At this speed



Rotatory Converter, Type Δ, IX., A.

Continuous-current side as motor for 300 volts, taking about 190 amperes. Three-phase side as generator at 200 volts, yielding 3 × 159 amperes, with frequency, 20 periods. Core-discs 117 slots, with two conductors per slot. Conductors 2·4, net section, 2·2 × 1·6 mm. Diameter of core-discs, 520 mm. Commutator 117 bars. Brush-holders, four sets, with five carbon brushes per set. Revolutions per minute, 600.

the measurements were: Continuous-current side, 295 volts, 153 amperes; on the three-phase side, 165 volts, 3 × 153 amperes. Then the output was changed to one of 235 amperes per phase of lagging current on a load of induction motors running light. The speed went up to 640 revolutions per minute (showing a weakening of the field), and the instruments measured :—Continuous-current side, 298 volts, 32 amperes; on the three-phase side, 157 volts, 3 × 235 amperes. To keep the speed, and therefore the frequency, constant under such conditions, the (shunt) excitation would need to be adjusted in accordance with the load and its lag. The pole-cores and yoke of this machine are of cast steel, each pole being wound with 3,200 turns of a copper wire of 2 sq. mm. section; the total resistance of the shunt winding being 80 ohms. The armature resistance from brush to brush is 0·028 ohm. The machine runs sparklessly with zero lead of the brushes. It will also run as a synchronous motor delivering continuous current sparklessly, with or without excitation of the field magnet, and with brushes set at zero, or set with either a large forward or a large backward lead. With a large backward lead, running synchronously, without excitation, at 627 revolutions per minute, giving out 46 amperes at 100 volts,

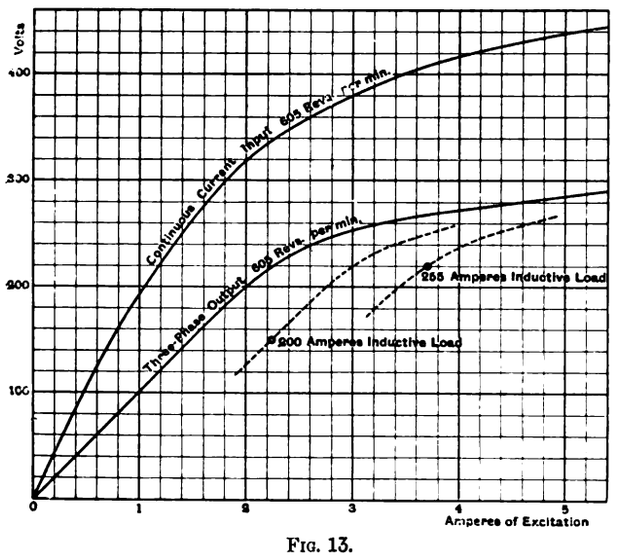

FIG. 13.

it took in three currents of 155 virtual amperes (largely wattless) at about 100 virtual volts at the three-phase side. The reactions in this curious case are exceedingly complicated.

Quite recently Mr. Gisbert Kapp* has re-examined the question of the influence on the conversion ratio and on the efficiency of changes in the distribution of the flux. With the theoretical case of a sine-law distribution he compares analytically other cases, equally unreal in fact, namely, those of a distribution of supposed uniform density over a limited arc of polar span. From his calculations it may be deduced that the conversion ratio will be the same as for the sine-law distribution if the poles are such that the breadth of their faces is about 70 per cent. of the pole-pitch. If the faces are broader the voltage ratio for a single-phase machine will be lower than 70·7 per cent., and the ampere ratio higher than 141·4 per cent. If the pole-breadth is reduced

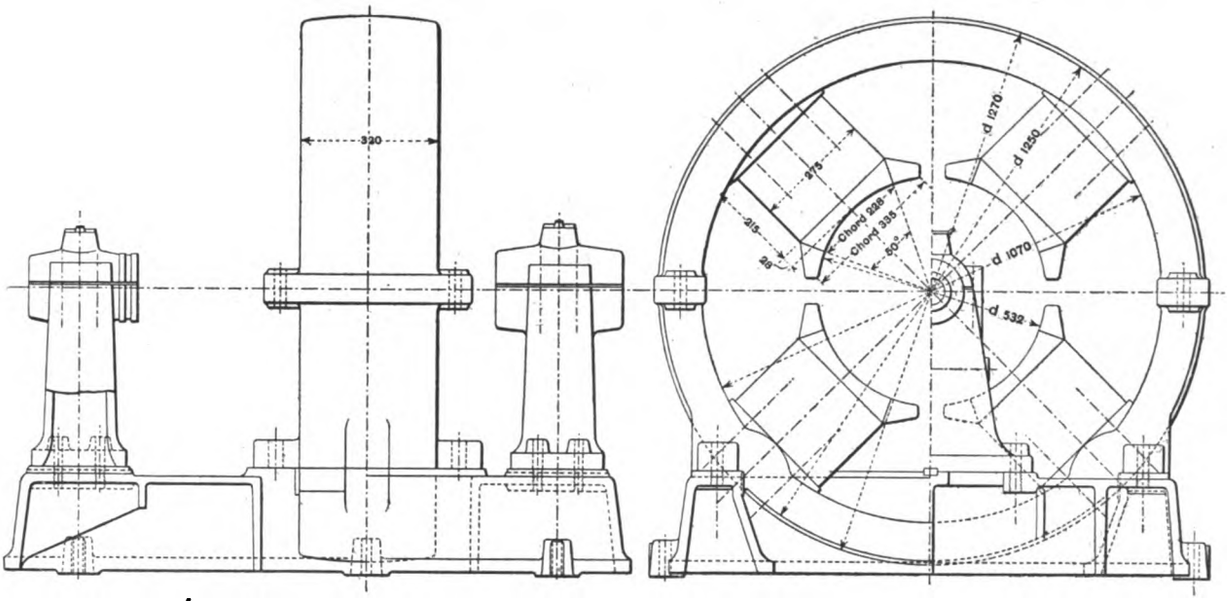

FIG. 12.—75 H.P. Rotatory Converter (Continuous Three-Phase), constructed by the Oerlikon Company.

to ⅔ of the pole-pitch, or to ½ the pole-pitch, the respective voltage percentages becomes as in Table VI. :—

Table VI.

Voltage for	Sine law.	Pole ratio, ⅔	Pole ratio, ½
Continuous current	100	100	100
Single-phase	70·7	75	82
Two-phase	70·7	75	82
Three-phase	61·2	65	71
Four-phase	50·0	53	58
Six-phase	35·35	37	42

M. Routin* has made another study of the effect of varying the pole-breadth, in a mathematical Paper, in which also he assumes the uniformity of the field beneath the poles. In the Oerlikon converter above described the pole-breadth was only 55 per cent. of the pitch, yet the voltage ratio was 66·6; showing that the field does not distribute itself uniformly, but is less concentrated, with fringing at the pole-tips.

Mr. Kapp has further treated the question of the limit of output for equal heating, for different pole-breadths, and for different angles of phase displacement in the currents. When the phase displacement is zero, the limiting output of a single-phase converter armature was (*see* above) 85 per cent. of that when used as a continuous-current armature simply, if the sine law is assumed. For pole-breadths of ⅔ and ½ respectively Kapp finds this increased to 88 and 95 per cent. This is equivalent to saying that if by concentration of field one makes the midway coils relatively more active, there will be for equal output less heating of the coils next to the connectors, and a less total heating. If there is a phase displacement such that cos $\phi = 0{\cdot}8$ ($\phi = 35$deg.), the percentage output for sine-law distribution is 69, but with pole-breadths ⅔ and ½ respectively this is raised to 73 and 80 per cent. But in practice the fringing of the field will reduce these latter values. For the more favourable cases of two-phase and three-phase converters these percentages of output for equal heating of the armature are greatly raised. The three-phase converter, assuming sine distribution and no phase displacement, has a limiting output 134 per cent. of that of the simple continuous-current armature. With pole-breadths of ⅔ and ½ the output rises to 138 and 144 per cent. respectively; and, if there is a phase dislocation such that cos $\phi = 0{\cdot}8$, to 117 and 126 respectively. For a two-phase converter the limiting output of 164 per cent., for the case of sine distribution and cos $\phi = 1$, becomes 167 and 170 per cent. respectively for pole-breadths of ⅔ and ½; whilst, when cos $\phi = 0{\cdot}8$, these numbers fall to 144 and 153 per cent. respectively.

A four-pole 30-kilowatt two-phase converter, constructed by Messrs. Brown, Boveri and Co., has been described to me by Mr. M. B. Field, who designed it for that firm. The armature is wound according to the scheme shown in Fig. 14. It has four poles (two wound, two unwound), and runs at 1,200 revolutions per minute, giving a frequency of 40 periods per second. Its efficiency is about 90 per cent. The input being two currents, of 415 working amperes each, in quadrature at 40 volts, the output is 500 amperes at 60 volts. The armature is a cylindrical drum-wound, in 56 slots, with two conductors per slot, as a singly re-entrant double winding, being cross-connected at the slip-rings to give four parallel circuits. At normal load, the excitation is such as to give a flux-density in armature core body of 7,800 lines per square centimetre, and in the teeth of 10,700 to 14,900. It runs (as exciter for some two-phase alternators) in parallel with some turbine-driven exciters and with a two-phase to continuous motor-generator. The ratio of conversion when running as two-phase motor did not alter greatly with the excitation, as the figures in Table VII. show:—

Table VII.

Exciting current.	Virtual volts between slip-rings.	Volts at commutator.	Ratio of conversion percentage.
2	18·5	30·0	60·8
3	27·0	43·0	62·7
4	34·0	53·0	64·2
5	41·0	62·0	65·1
6	46·5	68·5	67·8
8	53·0	77·0	68·5
10	56·5	82·0	68·8
12	59·0	86·0	68·6
14	62·0	88·5	71·0

It is, however, in America that the converter has found its application on the largest scale, for the purpose of supplying continuous

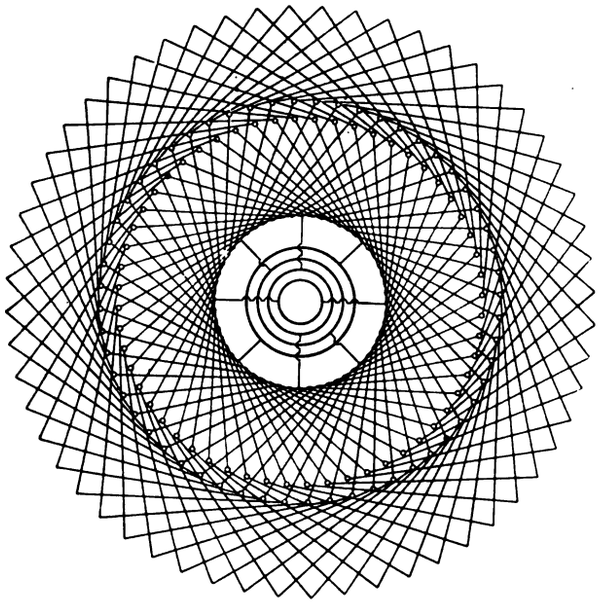

Fig. 14.

currents for tramway circuits, electric lighting systems, and electrolytic processes from distant power stations, whence the transmission is accomplished by polyphase currents at high voltage. These high-voltage currents, when they reach the receiving end, are first passed through transformers to reduce the pressure to a suitable lower voltage, and are then passed through the converters. The first large converters of the General Electric Co. were designed by Mr. Parshall on the lines of ordinary multipolar continuous-current generators, with powerful field magnets, and performed their functions well. Later, some designs were tried with relatively weaker field magnets, on the assumption that, in view of the lesser amount of armature reaction, commutation might be effected sufficiently well, in spite of a lighter construction. But, though a three-phase converter will, without any winding on the field magnets, operate by virtue of the armature reactions peculiar to the synchronous motor, the regulation in such machines leaves much to be desired, and the later designs exhibit a return toward the construction usual for multipolar continuous-current generators. By the kindness of Mr. Parshall and of Mr. Steinmetz, information as to a number of such large converters is available. At Niagara, where the Cataract Company generates two-phase current at 5,000 volts, converters are employed to supply continuous current for certain electrolytic processes—for the manufacture of caustic soda, and of aluminium. For the Pittsburg Reduction Co.'s aluminium works the General Electric Co. constructed a number of large converters. The two-phase current is first reduced by transformers to a pressure of 115 volts. At this pressure it is led into the converters, which give out the continuous current at 160 volts; the plant having a total capacity of over 10,000 amperes, equivalent to an output of about 2,000 H.P. At Schenectady were also constructed the six three-phase converters of 200 kilowatts each, for use in the power house at Brooklyn. As these machines are fairly typical of American practice, some information of their general construction is of interest. They are eight-pole 200-kilowatt machines, running at 375 revolutions per minute, the frequency employed being 25. The voltage on the three-phase side is 82·8; that on the continuous-current side 125, with an output of 1,600 amperes. The armature is 48in. in diameter, its core-length being 7in. between heads. This gives 4·95 sq. in. of peripheral surface per kilowatt.* The core-discs have 240 slots, with two conductors in each slot. Each lap of the drum winding is over 30 teeth. The gap measures 0·25in. from iron to iron. The commutator is 36in. in diameter, with 240 bars. The three slip-rings are each 18in. in diameter, 3½in. broad, and 1in. deep. The brushes are of carbon, eight sets of nine brushes each, and each brush with 1¼ sq. in. of contact surface. The brushes on the three-phase side are of copper. The flux through each pole-face is designed to be 4,380,000 lines at full load, the flux-density in the cast-steel pole-cores being then 80,000 lines per square inch. In the gap the pole-face density at full load is no less than 51,300 lines per square inch. In the teeth it reaches 135,600, and in the core-body 61,300. When running as a converter the brushes have no lead. When running on test as a continuous-current generator a lead equal to four bars of the commutator was necessary. The pole-breadth is 64·7 per cent. of the pole-pitch, and the voltage ratio of conversion

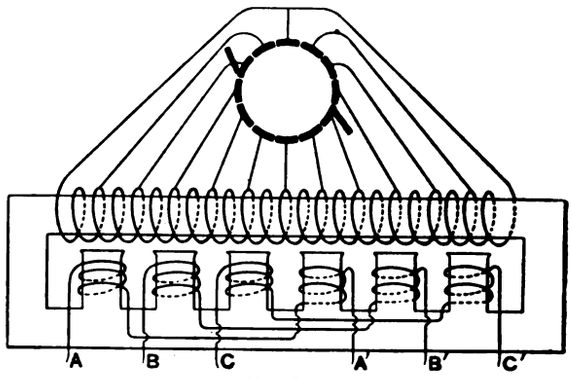

Fig. 16.

63·3 per cent. The C^2R loss in the converter armature at full load is 3,500 watts; it would be 6,250 if used as a continuous-current generator. The total armature loss as converter is 6,005 watts; as continuous-current generator, 9,130 watts. The temperature rise of the armature at full load is 27°C. as converter; as continuous-current generator it is 47°C. The temperature rise of the commutator at full load is 36°C. as converter; as continuous-current generator, 52deg.

Another three-phase converter, also constructed at the Schenectady works, is a 16-pole, 600-kilowatt machine, running at 188 revolutions per minute. In this machine the pole-breadth is 72 per cent. of the pole-pitch, yet the ratio of conversion is 71·8; the voltages at the respective sides being 115 and 160. The armature diameter is 100in., the core-length 8·25in., giving 4·3 sq. in. of peripheral surface per kilowatt. The temperature rise after 17 hours with a conversion output of 575 kilowatts was 15°C. in the armature, 23°C. in the field magnets. The average flux-density in the gap was 69,000 lines per square inch. To the same class of machines belong the four three-phase converters recently designed by Mr. Parshall (Fig. 15†) for the Central London Railway. These are 12-pole 900-kilowatt machines, running at 250 revolutions per minute. Each weighs about 30 tons; and their guaranteed efficiency will be 95 per

* The number of square inches of peripheral surface per kilowatt of output gives a basis for estimating to what degree in the design of an armture the specific utilisation of its materials has been carried. Modern dynamos of over 100 kilowatts output have from 4in. to 12 sq. in. per kilowatt. Old and small machines vary from 10 to as many as 25 sq. in. per kilowatt. In this estimate, the working part only of the peripheral surface is counted, being the length round the periphery multiplied by the total (gross) thickness of iron parallel to the shaft. These values apply to alternators and motors as well as to continuous-current dynamos.

† This cut is reproduced by the courtesy of *Engineering*, from the description given in that journal of the Central London Railway.

Digitized by Google

cent. at full load, 93 per cent. at half load. They are designed to take in their three alternating currents of 1,800 virtual amperes each at 310 virtual volts; the output on the continuous-current side being at 550 volts. The armature in each is a multipolar drum with 432 slots, and two conductors per slot; and, being lap-wound, has 24 circuits in parallel. It is connected down at 18 symmetrical points to the three slip-rings, there being six such connectors to each ring. Owing to the conditions imposed by the relations between voltage, speed, and size, it has been the practice in the States to design converters to operate at a frequency of 25, or at most 30, periods per second. But some of the General Electric Co.'s converters have been constructed for frequencies as high as 60, so as to be capable of being operated from lighting circuits. One such, a 16-pole 400 kilowatt two-phase converter, running at 450 revolutions per minute, has been recently described in the *Electrical World* (May, 1898).

One difficulty which has been experienced when operating converters in their application on the large scale—a difficulty which could hardly have been foreseen from the working of small isolated machines—is a tendency for them, when grouped in parallel, to set up a see-sawing interference of slow period, probably in consequence of armature reactions, similar to those which in certain types of alternators trouble their parallel running. Another puzzling defect is a similar tendency to hunt, observable

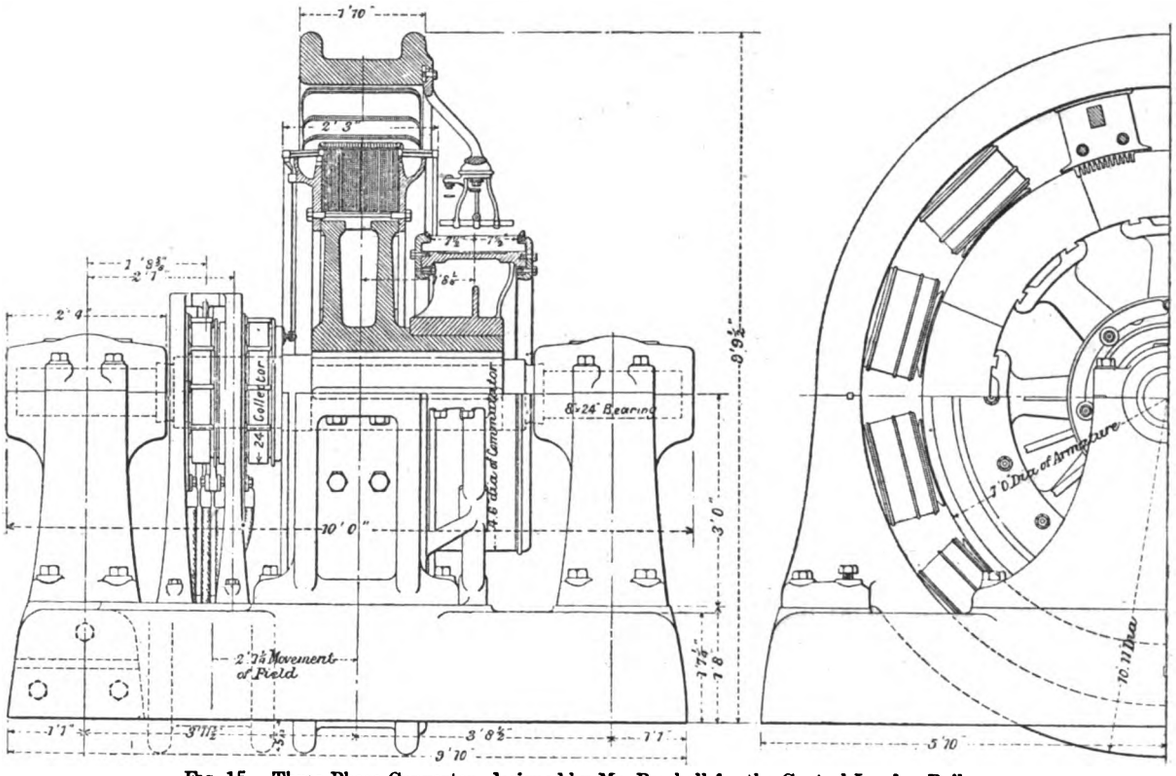

FIG. 15.—Three-Phase Converter, designed by Mr. Parshall for the Central London Railway.

when two converters are arranged in series at the two ends of a long three-phase line for the purpose of feeding continuous currents from one point to another. The cure for these troubles will probably be found in an analagous treatment to that adopted for securing good parallel running in alternators, namely, careful design, so as to prevent armature reactions from unduly distorting the magnetic field. But the point demands further investigation.

Before quitting the subject of converters, it is but right to refer to the existence of another class of rotating machine for effecting the same aim, and to which, for distinction, the name of *permutators* may be allotted. In this category are comprised those machines in which alternating currents (of one, two, or three phases) are first transmitted through a stationary part of the apparatus (a species of transformer), where they create in a re-entrant sectional winding a series of alternating currents which differ from one another in phase by small successive phase-angles; these currents being then led off to a commutator and commuted, section by section, into a continuous current. To fix ideas, consider Fig. 16, which is adapted from a recent article by Dr. J. Sahulka, in the *Zeitschrift für Elektrotechnik*. The lower part of the diagram represents the stationary transforming apparatus, having three pairs of projecting poles, wound with three circuits, A A', B B', and C C', to which are brought the three-phase primary currents. The action of these three-phase currents is to produce travelling polarities along the row of poles, and induce electromotive forces in the coils wound around the portion of the core above the six pole-faces. This winding, it will be observed, is electrically the precise equivalent of a Gramme ring. In an ordinary Gramme dynamo the ring revolves between two poles. Here, instead, the two polarities travel past the re-entrant winding. Under these circumstances, seeing that the commutator stands still, it is necessary that the brushes should be rotated synchronously in order that they may collect the continuous current. An apparatus essentially upon this principle was patented* by Zipernowsky and Deri in 1888, the brushes of this machine being rotated by a synchronously revolving unwound field magnet. How sparking was obviated does not appear. A further development in permutating machines was made by Messrs. Hutin and Leblanc, who turned the difficulty of the revolving brushes by the following device:—Upon the shaft of the synchronous motor is fixed the commutator and a series of slip-rings equal in number to the bars of the commutator, so that, though the commutator revolves, each segment may still be in connection with its corresponding point on the stationary re-entrant winding. The brushes may then be fixed as in ordinary machines. In *L'Electricien* of April 21, 1894, a detailed account is given by M. Aliamet of the further ideas of these inventors. It appears that 18 slip-rings are necessary in practice. A further account of an installation at Epinay is given by M. Guilbert in *La Lumière Electrique* of June 16, 1894. The sole advantage of machines of this type seems to be that they can transform and convert the three-phase currents from a high voltage without requiring the interposition of any other transformer. Their disadvantage in requiring many slip-rings is obvious. It is also very doubtful whether under varying conditions of use the sparking would not be excessive. Nevertheless, this type of converting machine is well deserving of the further attention of engineers. Probably there are cases where it is to be preferred to either the motor-dynamo group or the rotary converter proper. The motor-dynamo can transform the voltage as well as change the species of current. The converter can change the species of current, but only by adopting a fixed ratio of voltages. As it is inexpedient to operate a commutator at voltages over 1,000, the converter cannot be used in conjunction with a high-voltage polyphase transmission, except by the addition of a step-down polyphase transformer. It then becomes a question whether it is cheaper (regard being had to efficiency of operation as well as to prime cost) to instal the converter with the step-down transformer, or to substitute a pair of coupled machines as motor-dynamo. Experience shows that, at any rate in cases where the frequency of the supply is already sufficiently low, the former is generally the more economic. But it is quite probable that there are cases where the economic conditions of the problem may point to the permutator as affording a solution preferable to either motor-dynamo or converter.

* Specification No. 12,856 of 1898.

A THREE THOUSAND KILOWATT DYNAMO.

(*Communicated.*)

The rapid development of electric power for various purposes has made a demand for larger and larger units in the generating stations where this power is produced. A few years ago generators of 100 to 200 kilowatts capacity were considered enormous machines. There soon appeared, however, direct driven generators of 750 kilowatts, to be used in large railway plants in such cities as Chicago, Boston, St. Louis and Brooklyn. At the World's Fair, in 1893, the first 1,500 kilowatt generator made its appearance in the Intramural railway station. This machine was then considered a monster. This unit was soon adopted for many of the large street railway stations, notably in Chicago and Boston, and finally machines of 1,600 kilowatt were placed in the Kent Avenue Station in Brooklyn.

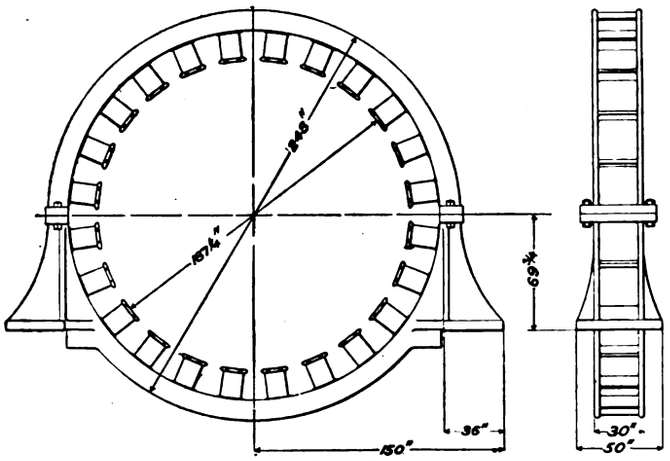

FIG. 1.—Frame of 3,000 Kilowatt Machine.

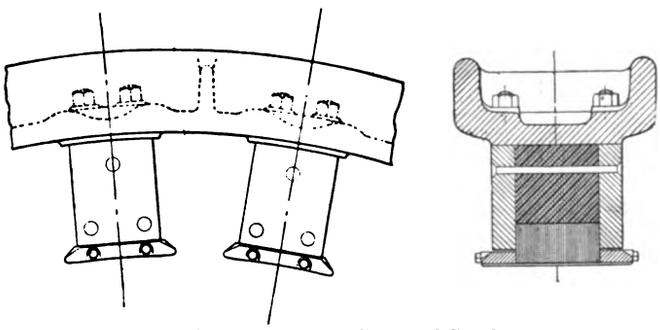

FIG. 2.—Field Magnet Cores and Spools.

Still later Louisville, Ky., purchased a 2,200 kilowatt generator. The Metropolitan Street Railway Co. of New York has recently placed an order for a number of 2,500 kilowatt alternating machines, and but a few months ago the Boston Elevated Railway Co., which succeeded the West End Street Railway Co. of that city, gave to the Walker Company of Cleveland the order for a 3,000-kilowatt machine.

All of these large machines are made to run at the very slow speed of from 75 to 80 revolutions per minute. It is true that the alternating-current machines built for the Cataract Construction Co., at Niagara Falls, have an output of 5,000 H.P. each, while the monster ordered by the Boston Elevated Railway Co. has an output of but 4,000 H.P. Nevertheless the 4,000 H.P. machine being built by the Walker Company is much larger than the alternators in use in the Niagara Falls power house, as the speed of the Boston machine is 75 revolutions per minute, while that of the Niagara machines is somewhere in the neighbourhood of 300 revolutions per minute.

As the construction of this 4,000 H.P. generator marks an era in the development of dynamo-electric machines, it may be interesting to electrical engineers, and those using electrical apparatus, to know its dimensions and general design. The total weight of the complete machine is 111½ tons. The frame is made of cast steel, and is circular in form, the diameter over all being 21ft. 7in. The weight of the frame alone, without the field-magnet cores for magnet spools, is about 25 tons. To the inside of the magnetic ring or frame are bolted 24 laminated steel magnet cores or pole-pieces, the total weight of which is about 15 tons. The inside diameter of the bore of these pole pieces, completed, is 15ft. 6in. The magnet cores are each provided with magnet spools, wound with shunt and series coils, in the usual way. The pole pieces are arranged to hold the magnet spools in place, and each core is bolted by four 3in. bolts to the inner surface of the magnet frame. The magnet frame is divided in halves, on a horizontal plane, and is mounted upon the foundation plates in such a manner that the whole frame may be made to slide lengthwise of the engine shaft far enough to uncover the armature windings, or to allow the individual magnet cores or field spools to be removed without separating the magnet frame.

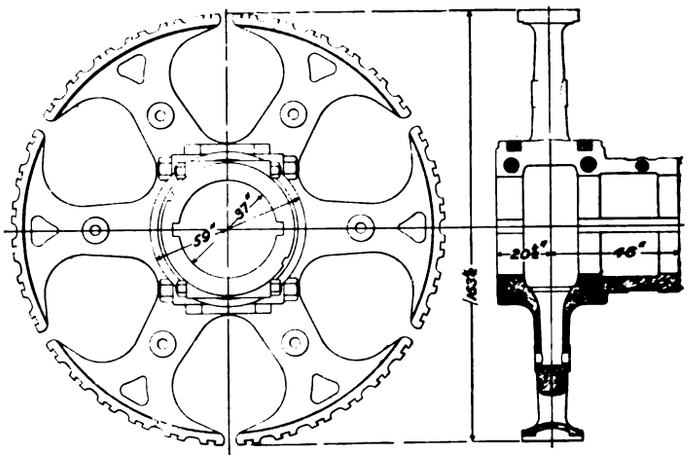

FIG. 3.—Armature Spider.

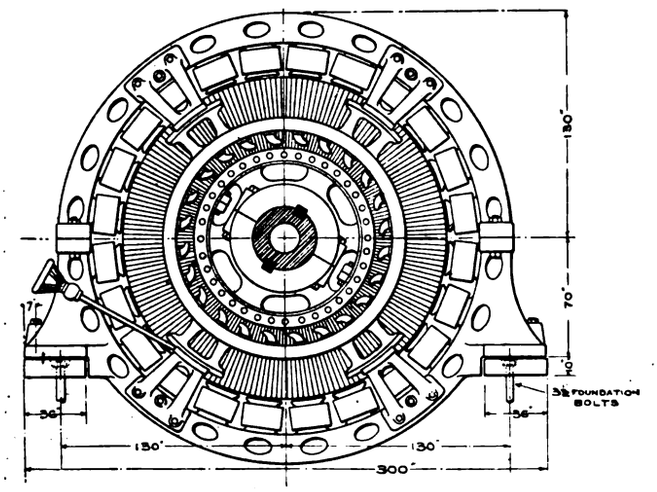
The armature spider of this machine is an interesting part of its construction. It is made in halves, like the hub of a flywheel, to be bolted together upon the shaft of the engine after it reaches its destination. If it had been made in one piece no railway car could be found large enough to ship it from Cleveland to Boston. The



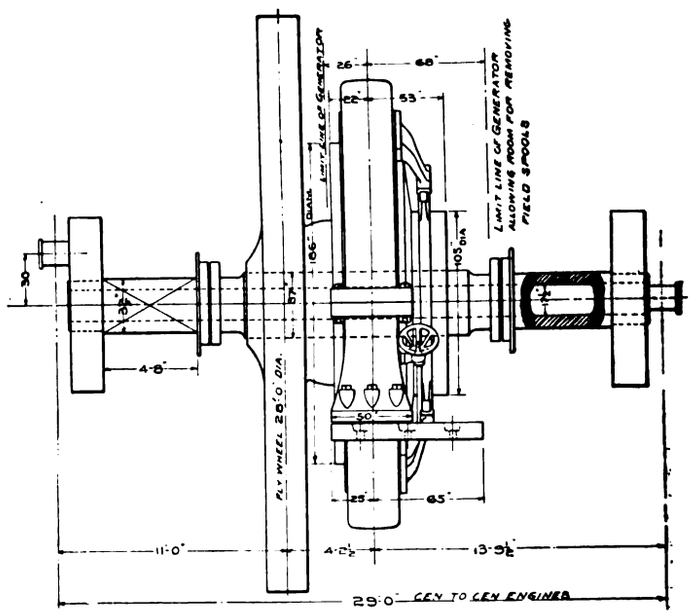


FIG. 4.—General Arrangement of 3,000 Kilowatt Generator.

Digitized by Google

armature hub weighs complete about 20 tons, and has an outside diameter before the laminations are in place of 13ft. After the engine is upon its foundations in Boston this armature spider will be mounted upon the engine shaft, which is itself 37in. in diameter. The laminations which form the armature core, the total weight of which is about 15 tons, will then be built upon the periphery of the armature spider. The slotting in the armature laminations will register accurately and provide, when completed, 594 slots. Insulation and windings will then be fitted into the slots and connected with the commutator.

The commutator itself is made up of 1,188 bars, and is 105in. in diameter. It is divided into halves for the purpose of shipment and ease of handling, and will be placed upon an extension of the armature hub after the latter is secured to the engine shaft. The great flywheel of the engine will be bolted directly to the armature hub near its periphery, in order that the regulating force of the wheel shall not be transmitted wholly through the shaft of the engine. This will relieve the armature shaft and its keys from the enormous strain to which they would otherwise be subjected.

The machine has been most carefully designed and an unusually large factor of safety provided for every part subjected to mechanical or electrical strain. Because of this the machine will be able to take twice its normal load for short periods of time without injury, and to carry a 50 per cent. overload for several hours. The greatest care has been taken to secure from the generator a higher percentage of efficiency than has thus far been attained in units of large size.

There seems to be no limit to the capacity to which these large generators can be carried. The development that has taken place thus far is an interesting study in view of what must ultimately come when we are compelled to provide means for the transmission of power for those large schemes of propulsion which are awaiting the application of electricity in place of steam. What will be the limit to the size of machines required when our main-line steam railways are operated by electricity?

INSTITUTION OF ELECTRICAL ENGINEERS REVISED ARTICLES OF ASSOCIATION.

At a Special General Meeting of Members only, held on November 3rd, a revised set of Articles of Association were considered and passed, and at a subsequent Special General Meeting on November 18th, this resolution was duly confirmed. The new Articles come into force on January 1, 1899. The following are some of the more important alterations and additions; in some cases the new and the old Articles are arranged in parallel columns to facilitate comparison:—

Abreviated Titles.

9. The authorised abbreviations indicating the class in the Institution to which any honorary member, member, associate member, associate, or student belongs shall be as follows:—For an honorary member, *Hon.* M.I.E.E.; for a member, M.I.E.E.; for an associate member, A.M.I.E.E.; for an associate, A.I.E.E.; and for a student, *Student* I.E.E.

Diplomas.

10. Subject to such regulations as the Council may from time to time prescribe, the Council may issue to any member or associate member a certificate showing the class to which he belongs. Every such certificate shall be according to the form F in the schedule, or such modification thereof as may from time to time be approved by the Council, and shall remain the property of, and shall on demand be returned to, the Institution.

Qualification and Election of Members, &c.

Old Articles.	New Articles.
9. *Members.*—Every Member shall come within one of the following descriptions:—	12. *Members.*—Every new member (*i.e.*, members not on the register as members on December 31, 1898) shall, whether admitted by election or transfer, be at least 25 years of age, and come within one of the following descriptions:—
(*a*) He shall have been regularly educated as a telegraph engineer, or electrical engineer or electrician (according to the usual routine of pupilage), and have had subsequent employment for at least five years in responsible situations;	(*a*) He shall have been educated as an electrical engineer or electrician in a manner which shall satisfy the Council, and either (1) shall have had subsequent employment in the application of electricity for at least five years in situations of superior responsibility, and shall be actually engaged in such a situation at the time of his application for election or transfer, or (2) shall be in practice, and shall have practised on his own account in the profession of an electrical engineer or electrician for at least five years, and shall have acquired sufficient eminence in the same; or
(*b*) Or he shall have practised on his own account in the profession of a telegraph engineer, electrical engineer, or electrician, for at least two years, and have acquired a degree of eminence in the same;	(*b*) being, either in a position of superior responsibility, or in practice on his own account in the profession of an electrical engineer or electrician, he shall have held such responsible position or positions, or shall have so practised on his own account that he has acquired sufficient eminence in the said profession, during a period or periods which, singly or in the aggregate, shall amount to seven years; or
(*c*) Or he shall be so intimately associated with electrical or telegraph science that the Council consider his admission to membership would conduce to the interests of the Institution.	(*c*) being an associate member, he shall have gained the senior premium in any year for a paper read at an ordinary general meeting of the Institution; or
	(*d*) he shall be so prominently associated with the objects of the Institution that the Council consider his admission to membership would conduce to its interests.
10. *Associates* shall, except in the case of those transferred from the class of students, be persons of more than 21 years of age; and all associates, whether so transferred or not, shall be persons who are connected with electrical or telegraphic science or engineering, either professionally or otherwise, or who are so intimately associated with electrical or telegraphic science that the Council consider their admission as associates would conduce to the interests of the Institution.	13. *Associate Members.*—Every associate member shall be either an electrical engineer or an electrician, and shall be at least 25 years of age, and, whether admitted by election or by transfer, shall come within one of the following descriptions:—(*a*) He shall have been on the register as an associate on December 31, 1898; or (*b*) he shall have been educated as an electrical engineer or electrician in a manner which shall satisfy the Council, and either (1) he shall have had subsequent employment for at least two years in a responsible situation as an electrical engineer or electrician, and shall be actually engaged in such a situation at the time of his application for election or transfer; (2) he shall have been engaged for at least five years in one of the branches of electrical engineering, and shall be actually so engaged at the time of his application, and shall afford satisfactory proof to the Council of his fitness for election; or (3), being an associate, he shall have gained a premium in any year for a paper read at an ordinary general meeting of the Institution.
	15. *Associates.*—Associates shall be persons, more than 21 years of age, who are interested in, or connected with, electrical science or engineering or who are so associated with the application of electricity that the Council consider their admission as associates would conduce to the interests of the Institution.

The qualifications for foreign members and honorary members remain the same. A student may not remain in the student class for longer than three years, unless he has not attained the age of 22 (not 21 as formerly), at the end of that time.

Formerly, every candidate for election into the Institution (except as honorary member) needed only a proposer and seconder, both members. Now:—

If he be proposed for election to the class of members or of foreign members, by three members or by two members and two associate members; or,

If he be proposed for election to the class of associate members, by two members or by one member and two associate members; or,

If he be proposed for election to the class of associates, by two members or by three associate members or associates.

This rule may, however, be waived in the case of candidates residing abroad, if they be nominated by the Local Honorary Secretary and satisfy the Council as to their eligibility. Students need only one member as proposer.

As regards transfers, the old rules read:—

The Council shall decide upon the application for transferring any candidate from one class to another.

In the new Articles the following is added:—

but, except as hereinafter provided, every candidate for transfer to any class shall be duly nominated for such transfer, in writing and from personal knowledge, by two members; and his candidature shall be supported, in writing, by as many members, associate members, or associates as would have been required by Article 18 had he been a candidate for direct election to the class to which he seeks to be transferred. [Excepting that an associate who shall have been on the register as an associate on December 31, 1898, and who can prove to the satisfaction of the Council that he is duly qualified according to the preamble of Article 13, may be transferred to the class of associate members on receipt of his personal application alone, in writing.]

Facilities are also given to candidates abroad, as in the the case of election.

Contributions to the Funds.

The yearly contributions to the funds remain the same for those who are already connected with the Institution, and do not wish to be transferred. For those elected after December 31, 1898, the existing subscriptions in pounds are to be paid in guineas, with the exception of students whose annual sub-

Digitized by Google

scription is raised from a half to a whole guinea. The entrance fee for members is raised from £3 to 3 guineas, and for associates diminished from 30s. to 1 guinea. Associate members are to pay 2 guineas entrance fee, and a like sum as annual subscription. As before, lower fees are payable by those living abroad nine months in the year. Associates now transferred to associate membership will have to pay 12s. to make up the 2 guinea entrance fee, and pay the annual 2 guineas subscription, just as newly-elected associate members.

The fees for life-membership have been considerably raised:—

Old Articles.	New Articles.
25. Any member elected before December 31, 1891, may compound for his annual subscription by the payment to the Institution in one sum of £21 if resident in the United Kingdom, or, if resident abroad, by the payment in one sum of £10. Any member elected after the said date may compound by the payment in one sum of £25 if resident in the United Kingdom, or, if resident abroad, by the payment in one sum of £10. Any associate elected before December 31, 1891, may compound for his annual subscription by the payment in one sum of £10; or, if elected after the said date, by the payment in one sum of £12. 10s. if resident in the United Kingdom, or of £10 if resident abroad. Any foreign member may similarly compound by the payment in one sum of £10. .	28. Any member, associate member, foreign member, or associate may, after December 31, 1898, compound for his annual subscription by the payment to the Institution in one sum of £42. Provided that if any such member, associate member, foreign member, or associate has, as a member, associate member, foreign member, or associate, paid to the Institution or its predecessors more than ten annual subscriptions, such sum of £42 shall be reduced by the deduction of £1. 1s. for every year after the tenth year during which he shall have paid such annual subscriptions. . . . Provided that any existing member, foreign member, or associate may, until the date of the annual general meeting in 1899, compound upon the terms specified in Article 25 of the existing Articles of Association.
22. An associate resident in the United Kingdom who has compounded by payment of £10 shall, if transferred to the class of members before December 31, 1891, pay either an additional composition of £11 or an annual subscription of £1. 1s. If transferred after the said date, he shall pay either an additional composition of £15 or an annual subscription of £2.	30. An associate resident in the United Kingdom who has compounded by payment to the Institution or its predecessors of £10 or of £12. 10s. shall, if transferred to the class of members before December 31, 1891, pay an annual subscription of £1. 1s.; if transferred after the said date and before December 31, 1898, pay an annual subscription of £2; or, if transferred after the last-named date, either directly to the said class of members or after passing through the class of associate members, he shall pay an annual subscription of £2. 2s.; if transferred to the class of associate members, he shall pay an annual subscription of £1. 1s. . . .

Annual General Meeting.

The Annual General Meeting is to be the last meeting of the session (on or about June 1st) instead of the meeting next previous to Christmas Eve.

Local Sections.

65. The Council may, at their discretion, upon receipt of a request to that effect from a sufficient number of honorary members, members, associate members, foreign members, or associates, resident in any district, create a local section of the Institution in such district, and they shall also have power to dissolve such section at any time after it has been formed.

66. Each local section shall be constituted, and its affairs shall be carried on, in accordance with the rules and regulations to be laid down from time to time by the Council, and it shall elect annually for its chairman or president a member of the Institution, who, during his period of office as chairman or president of the section, shall be *ex-officio* a member of Council.

67. The Council may, at their discretion, upon receipt of a request to that effect from any local society with objects kindred to those of the Institution, arrange for the union, alliance, or incorporation of such society with the Institution; and may also, if they think fit, remit or reduce the entrance fees of the members of such society at the time of union, alliance or incorporation.

The Council are empowered to publish Papers read at the meetings of the local sections, just as in the case of Papers read at ordinary meetings.

Copyright of Papers.

73. Every Paper presented to the Institution, and accepted for reading or for publication in the *Journal*, and the copyright thereof, shall be the property of the Institution, unless there shall have been some previous arrangment to the contrary. But the Council, in such cases as they may think fit, shall have power to release or surrender their rights in respect of any such Paper, or the copyright thereof.

Common Seal.

76. The Council may provide a common seal of the Institution, and make rules for the safe custody of the same, and for the use thereof, and it shall never be used except by the authority of the Council previously given, and in the presence of two members of the Council at the least, who shall sign every instrument to which the seal is affixed, and every such instrument shall be countersigned by the secretary, or some other person appointed by the Council.

77. The Institution, acting by the Council, may exercise all the powers given by the Companies' Seals Act, 1864.

ELECTRICITY WORKS ACCOUNTS.

The Newcastle and District Electric Lighting Co. (Limited).

Our tables this week present the analyses of the accounts of the Newcastle and District Electric Lighting Co. and of the Norwich Electricity Co.:—

The electric lighting undertaking of the former Company started working in January, 1890. Good progress continues to be made in almost every respect—viz., in custom, economy of working and in the financial results.

The authorised share capital of the Company stands at £100,000, while the borrowing powers are to the extent of half the paid-up capital. The share capital paid up and received is £60,501, and the loans stand at £8,900, making a total received capital of £69,401. Up to December 31st last the total expenditure had reached £76,799, representing £60·4 per kilowatt of generating capacity of plant installed.

During 1897 an equivalent of 5,000 8-c.p. lamps had been added to the circuit, raising the total lamp connection to 33,000 (8 c.p.). The output for the year was 600,972 units sold, being an increase of 13 per cent. over the output of 1896.

While the nominal price charged has not been altered, the average price obtained has *risen* from 4·4d. to 4·5d. per unit. Economies in the management and property charges have, in spite of increased works costs, reduced the total costs from 2·29d. to 2·26d. per unit. Generation costs have decidedly risen.

A working profit of £5,675, representing 8·04 per cent. of the mean expended capital, has been made. Out of this and the balance of £140 from 1896 £600 has been carried to the depreciation fund, £282 to the reserve fund, and £522 paid as interest on loans, leaving a balance out of which a dividend of 7½ per cent. per annum has been paid.

An idea of the progress which has marked the undertaking may be gathered from the following record of the output:—In 1891 the number of units sold was 206,000; in 1892, 290,500; in 1893, 388,500; 1894, 431,000; 1895, 472,000; 1896, 541,139; and in 1897, 600,972.

The Norwich Electricity Co.

Starting supply in October, 1893, the Norwich undertaking has completed its fourth year of working.

The total authorised capital is £100,000, of which £71,150 has been received, £45,650 from the paid-up share capital; £19,500 upon the Four per Cent. Debenture Bonds, and £6,000 by a bank loan. The total expenditure as capital has amounted to £79,502, or about £89 per kilowatt capacity. During the year 221 consumers have been connected to the mains, thus raising the equivalent 8 c.p. lamp connection from 21,000 to 29,000, or 38 per cent. The corresponding output was 572,000 units sold, representing an increase over that of 1896 of 31 per cent. An average price per unit of 4·86d. has been obtained, as compared with 5·29d. for 1896. The total costs per unit have fallen slightly through economies in works costs since the management and property charges have risen.

Owing to the reduction in the revenue, the ratio of costs to revenue has risen slightly to 41·2 per cent. However, a working profit of £6,801 has been made, and this, together with £444 from 1896, has enabled £2,500 to be set aside to the depreciation fund, £1,000 to the reserve fund and £805 to be paid as interest on loans. A balance available for distribution has thus been left of £2,940, out of which a dividend of 5½ per cent. for the year has been paid, and £452 carried forward.

To promote custom, the Directors have introduced a system of free wiring, charging to customers so acquired 8d. and 4d., instead of 7d. and 3½d. per unit. Motors are also supplied on the three years' hire-purchase system. During 1897 20 additional motors, representing an aggregate of 60 H.P., were connected, being a larger increase than that of any preceding year.

The Electrician.

he Oldest Electrical Journal (established as a weekly Journal 1861—1876).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	15s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Removals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 8s. 6d., post free

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Considerable changes have been effected in the Articles of Association of the Institution of Electrical Engineers, changes which should increase the importance and prestige of the Society, and confer benefit on its individual members. We publish in another column a fairly complete *resumé* of the alterations which will come into force on January 1, 1899, and it will at once be noticed that those which are likely to bear most fruit are the introduction of the new class of Associate Members, and the proposed formation of "Local Sections" of the Institution. With regard to the former, it will be recognised that our younger Institution is again flattering the progenitor of all engineering societies by an imitation of its methods. Men who are in the future to be elected as Associate Members must be electrical engineers or electricians by training and by occupation, and the restrictions in the new Article 15 make it essential that they should have had considerable experience in their profession. Exceptions are made only in the case of those Associates who have shown superior merit by obtaining a premium for a Paper read before the Institution, and of those who are at present on the register. The latter exception is, it must be admitted, a fair one, for although no one who was ineligible as Associate under the old regulations is eligible under the new, the better men who would be Associates under the old rules are offered a higher rank, and this will necessarily in the course of time cause the Associate class to loose caste, as it were. It will also be noticed that the qualifications for membership have been placed higher by requiring a five years' occupation of situations of *superior* responsibility under the first clause, or, in the optional clause, by raising the time the candidate must have practised on his own account from two to five years. A minimum age limit has also been added. This equality of conditions for those who are employed in responsible posts and those who are their own masters is commendable, and is representative of the spirit pervading the engineering world at the present time. The superior qualifications required for membership will also, of course, leave many better men in the Associate Member

Digitized by Google

class who would not previously have remained Associates. One question may in all fairness be put, however. What advantages will the Associate Member have over the Associate in return for his greater ability and higher fees, except the right of increasing by one the number of letters following his name? The Member has always had the advantage of being able to vote on questions of change of the Articles of Association, but the Associate Member will not possess this privilege, he and the Associate being, it appears, exactly on a similar footing so far as voting power is concerned. In the Institution of Civil Engineers the Associate Member has all the voting powers of a full Member, while the Associate (except in the case of some few individuals) is not entitled to the privileges of corporate membership. This is certainly more just, as the difference drawn outside the Institution between a M.Inst.C.E. and an Assoc.M.Inst.C.E. is much greater than that between an Associate Member and an Associate. The class of Associates of the Institution of Electrical Engineers has one more point of dissimilarity with that of the Institution of Civil Engineers. In the latter Institution a civil engineer by profession who cannot or will not qualify for an Associate Member, cannot belong to the society as an Associate, for this class is confined to those who are not professional engineers. In the Institution of Electrical Engineers anyone connected with electrical engineering can be an Associate if the Council approve of him.

We come now to the other important advance, viz., the creation of local sections. This should certainly be encouraged; in fact, it should have been encouraged at least five years ago, before the formation of the Northern Society of Electrical Engineers. The Northern Society was formed with no idea of rivalry or opposition to the older institution, but merely to give electrical engineers in the North, who were prevented from attending the meetings of the Institution in the metropolis, an opportunity of assembling and exchanging views. Had there been a possibility of forming a "Local Section" in 1893, the Northern Society would probably have taken that form, and, although the quality of the Papers read before this society has always been of a very high standard, it must be allowed that its management might have been better if the Society had been under the motherly wing of the Institution. One cannot help reading in No. 67 of the new Articles, and in the Rule making the presidents of local societies *ex-officio* members of the Council, a distinct offer to the Northern Society of Electrical Engineers.

A radical change of this sort in the constitution of a popular society cannot altogether escape criticism, and there are some cases where real or apparent hardship might be instanced. Among them we may mention the large increase in the sums required from some of those who wish to compound for their annual subscription. For Members, Associate Members and Associates who have no intention of being transferred the matter is more or less a financial speculation and a fair one. But we wish to point only to the case of those Associates who have already compounded for their annual subscription. If they are content to remain in their present class after the best men have moved from it, they need pay no more; but if they feel impelled, as many naturally will, to change their state and become Associate Members they will be obliged either to make up to 40 guineas the sum they have already paid (£10 or £12. 10s.) as a composition for all future subscriptions, or they will have to pay a regular annual subscription of a guinea under Article 30. Students may also complain. Their fee is doubled, while the fees of the other classes are only raised from pounds to guineas. They must remember, however, that the subscription they have paid hitherto has been extremely low, not sufficient to cover the cost of the journal. Students, if they joined before 22 years of age, must, contrary to the custom at the Institution of Civil Engineers, reach associate membership *vid* associateship, the maximum student's age being in some cases 22, while the minimum age for Associate Members is 25. The last fact is, however, unimportant, except in so far as it will increase the number of transfers the Council has to attend to.

We are glad to see the encouragement given to associate members and associates to read premium Papers, by the qualifications for membership and associate membership. These will, no doubt, prove a greater inducement to them to present Papers to the Institution than the mere money value of the premiums themselves. Taken as a whole, the new Articles of Association are a decided improvement on the old ones, and we trust that they will add to the prosperity of the Institution of Electrical Engineers.

ELECTRIC LIGHTING AND TRACTION NOTICES.

Subjoined is a complete list of the electric lighting and traction notices for the session of 1899. Of the Provisional Order notices 13 are metropolitan and 94 provincial, while six of the Bills affect the London area and 21 the provinces. The most noticeable feature on the present occasion is the number of Bills promoted by local authorities already in possession of electric lighting powers, but who are anxious to extend their area of supply, or to obtain additional powers in connection with their electricity supply schemes. In addition to the Bill of the General Power Distributing Co., which is to be resumed at the stage at which it was left in the last session, there are seven other Bills for powers to generate and supply electric current "in bulk," and the Midland Electric Corporation for Power Distribution, no doubt encouraged by their partial success of last year, are endeavouring to obtain a Provisional Order for several towns and districts in Worcestershire and Staffordshire. Three companies are seeking to obtain the right of competing with the City of London Co., while the Vestries of Bermondsey and St. Marylebone, undeterred by the failures of last year, are proceeding by Provisional Order and Private Bill respectively. In the case of Marylebone, overtures have, we understand, been made by the Vestry to the Metropolitan Electric Supply Co. for the purchase of so much of the Company's undertaking as lies within the parish of Marylebone.

As regards electric traction schemes, we need only draw attention to the great increase in the number of notices compared with 1898. There are no Provisional Orders which affect the metropolitan area, and but 15 hail from the provinces; nine of the Bills, however, deal with London and suburban projects, and the remaining 30 are provincial. It would, therefore, appear that applications under the Light Railways Act, so much favoured by companies, have a rather stimulating effect upon municipal authorities, and tend to increase the number of electric traction Provisional Orders and Bills. We give below the figures for the last eight years:—

	1892.	1893.	1894.	1895.	1896.	1897.	1898.	1899.
Lighting	34	20	32	32	41	61	98	134
Traction	15	15	17	13	37	61	45	54

West Bromwich, Amblecote, Brierley Hill, Handsworth, Perry Barr, Quarry Bank, Smethwick, Kingswinford, Aldridge, Great Barr, Pelsall and Rushall (in Staffordshire), and Dudley, Lye, Wollescote, Oldbury, Stourbridge and Halesowen (in Worcestershire)	Midland Electric Corporation for Power Distribution.
Worksop	District Council.
Ystradyfodwg (Glam.)	Mardy Electric Lighting Co.

PARLIAMENTARY BILLS.

METROPOLIS.

Name of Applicant.	Powers sought.
Central Electric Supply Co.	To generate and supply electric current in "bulk" and to erect generating station in parish of St. Marylebone.
County of London Electric Lighting Co.	To compulsorily acquire certain lands in parishes of St. James's (Camberwell), Wandsworth, St. Luke's (Middlesex), St. James's (Southwark) and other districts.
Kensington and Knightsbridge Electric Lighting Co. and Nottinghill Electric Lighting Co.	To acquire lands for electricity generating station in parish of Hammersmith and to lay mains therefrom into the areas of supply of both companies.
Marylebone Vestry	To purchase undertaking of Metropolitan Electric Supply Co. in Marylebone district and to generate and supply electric current, &c.
Metropolitan Electric Supply Co.	To supply electric current in City of London. (*See* also Provisional Orders.)
St. James's and Pall Mall Electric Lighting Co.	To acquire land compulsorily in parish of St. James's (Westminster), to erect electricity generating station, &c.

THE PROVINCES.

Barking (Essex) District Council	To purchase, sell and let on hire electric fittings.
Birmingham Corporation	To purchase undertaking of Birmingham Electric Supply Co. and to extend area of supply.
Bootle Corporation	To supply electric current outside Borough area, and to sell, deal and let on hire electrical apparatus.
Cobham Gas Co.	To enable company to obtain electric lighting powers.
Crowborough and District Gas Co.	To incorporate company to acquire undertakings of Crowborough District Gas and Mayfield District Gas Light Companies, and to generate and supply electric current.
Dublin Corporation	To extend electric lighting area, &c.
Hastings and St. Leonards Gas Co.	To accept transfers of any electric lighting powers affecting Hastings or Bexhill.
Highland Water Power Co.	To incorporate company to establish elec. supply works, &c., in Invernesshire, &c.
Lancashire Electric Power Co.	To incorporate company to generate and supply electricity within parts of the counties of Lancaster and Chester (including Liverpool, Manchester, Preston, Burnley, Bolton, Blackburn, Oldham, Widnes, St. Helens, Stockport, Macclesfield, Birkenhead, Salford, Accrington and Darwen).
Leicestershire and Warwickshire Electric Supply Co.	To incorporate company to generate and supply electric current within parts of counties of Leicester, Warwick and Derby (including Birmingham, Leicester, Coventry, Sutton Coldfield, Rugby, Leamington, Warwick, Tamworth, Coleshill, Nuneaton, Burton, Lichfield, Derby, &c.), and to enter into agreements with local authorities and others.
Loughborough Corporation	To supply electric current, sell and let on hire electric motors, &c.
Loughborough Gas Co.	To empower application for Provisional Order.
Manchester Corporation	To light *culs de sac*, purchase and let on hire electric motors and electrical apparatus, establish insurance fund, and to borrow additional capital.

Digitized by Google

Name of Applicant.	Powers sought.
Mid Kent Gas Co.	To incorporate and empower company to apply for electric lighting powers, &c.
Rushden and Higham Ferrers Gas Co.	To empower company to apply for Provisional Order.
St. Albans Gas Co. ..	To empower company to take transfer of St. Albans Provisional Order.
Shirebrook & District Gas Co.	To empower company to apply for Provisional Order.
South Lancashire and Cheshire Electricity Co.	To incorporate company, to generate and supply electric current within parts of the counties of Lancaster and Chester (including St Helen's, Widnes, Warrington, Wigan, Liverpool, Runcorn, Eccles, and Bolton), and to enter into agreements with local authorities and others.
Walker and Wallsend's Union Gas Co.	To generate and supply electric current.
Wallasey District Council	To sell, deal in and let on hire electric light fittings.
Whitehaven Corporation	To extend electric lighting area.

ELECTRIC TRACTION NOTICES.

PROVISIONAL ORDERS.

THE PROVINCES.

Barking District Council	To construct, work or lease tramways, to adopt electric traction, &c.
British Electric Traction Co.	To construct electric tramways in Birkdale and Southport, &c.
Burt (Frederick) and Co.	To construct and work electric tramways in Exeter and district.
Clayton District Council.	To construct and work tramways, use mechanical traction, &c.
Dudley and Wolverhampton Tramways Co.	To equip tramways electrically, &c.
Eccles Corporation...	To work tramways, employ electric traction, &c.
Gravesend, Rosherville & Northfleet Tramways Co.	To construct additional tramways, introduce electric traction, to sell undertaking to Drake and Gorham Electric Power & Traction Co., &c.
Ilford District Council.	To construct and work tramways, to employ mechanical traction, &c.
Ilkeston Corporation	To construct and work tramways, adopt mechanical traction, &c.
Ipswich Tramways Co.	To construct additional tramways, to use electric traction, and to sell undertaking to Drake and Gorham Electric Power and Traction Co.
Queensbury District Council.	To construct and work tramways, to adopt mechanical traction, &c.
Reading Corporation.	To construct and work tramways, use electric traction, &c.
Southport Corporation.	To construct and work tramways, to use electric traction, &c.
Weston-super-Mare Tramways Co.	To construct additional tramways, to use electric traction, &c.
Wrexham Tramways Co.	To construct additional tramways, to employ electric traction, and to sell undertaking to Drake and Gorham Electric Power and Traction Co.

PARLIAMENTARY BILLS.

THE METROPOLIS.

Baker-st. and Waterloo Railway Co.	To extend time, to acquire lands, &c.
Brompton and Piccadilly Circus Railway Co.	To construct new railways, to enable Metropolitan District Railway Co. to subscribe and guarantee interest on capital, &c.
Central London Railway Co.	To extend time, to acquire additional land, &c.
Charing-cross, Euston and Hampstead Railway Co.	To construct new railways, alter authorised line, to enter into agreements with Midland Railway and Baker-street and Waterloo Railway Companies, &c.
Great Northern and Strand Railway Co.	To incorporate Co., to construct electric railway from Wood Green to the Fleet-street end of the Strand.
London United Tramways	To employ electric traction, to enter into agreement with London County Council, &c.
London, Walthamstow and Epping Forest Railway Co.	To enable Great Eastern Railway Co. to construct railway, to guarantee interest, &c.
North West London Railway Co.	To incorporate Co. and to construct electric railway from Marble Arch to Cricklewood.
Thames Ferry Co.	To incorporate Co., to construct ferry on sub-merged rails across the Thames, between Greenwich and Millwall, and to use electric traction.

THE PROVINCES.

Birkenhead Corporation	To construct and work tramways, to adopt electric traction, &c.
Blackpool Corporation	To construct tramways, to enter into agreement with Blackpool, St. Anne's and Lytham Tramways Co., as to supply of electric current.
British Electric Traction Co.	To construct electric tramways in Bexhill, Hastings, &c.
British Electric Traction Co.	To construct electric tramways in Airdrie and Coatbridge, &c.
Darwen Corporation	To construct, work or lease tramways, adopt electric traction, &c.
Derby Corporation...	To acquire, work or lease tramways, adopt electric traction, &c.
Gateshead and District Tramways Co.	To construct additional tramways, to employ electric traction, &c.
Glasgow Corporation	To construct and work tramways within and without municipal area, to use electric traction, &c.
Great Grimsby Street Tramways Co.	To construct tramways, use electric traction, &c.
Great Yarmouth Corporation	To construct and electrically equip tramways, &c.
Hastings Corporation	To construct and work tramways, to use electric traction, &c.
Kirkcaldy Corporation	To construct electric tramways, &c.
Leeds Corporation	To construct additional tramways, to adopt mechanical traction, &c.
Liverpool Overhead Tramways Co.	To take on lease and work Waterloo-with-Seaforth and Great Crosby tramways, &c.
Manchester Corporation	To confirm agreements with outside authorities as to leasing tramways, to adopt mechanical traction, &c.
Moss Side District Council	To equip tramways electrically within and without municipal area, &c.
Newcastle-on-Tyne Corporation	To construct new and alter existing tramways, to employ electric traction, to work or lease lines, &c.
Nottingham Corporation	To construct and work tramways, to use electric traction, &c.
Oldham Corporation	To construct tramways, to adopt electric traction, to enter into agreements with neighbouring local authorities, &c.
Salford Corporation	To construct new tramways, to sanction agreements with adjoining local authorities, to employ electric traction, &c.
Southport and Lytham Tramrd. Co.	To incorporate company, to use electric traction, &c.
Southport Tramways Co.	To construct tramways, use electric traction, &c.
South Staffordshire Tramways Co.	To lease tramways, to introduce electric or mechanical traction, &c.
Stockport Corporation	To purchase and work tramways, to introduce electrical or mechanical traction.
Stretford District Council	To equip tramways electrically, &c.
Sunderland Corporation	To construct new and alter existing tramways, to adopt electric traction, &c.
Withington District Council	To equip tramways electrically, &c.
Wallasey District Council	To construct and alter existing tramways, to use electric traction, &c.
Wolverhampton Corporation	To construct, work or lease tramways, to employ electric traction, &c.
Wolverhampton Tramways Co.	To use electric traction, &c.

CORRESPONDENCE.

THE BRIGHTON BREAKDOWN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am among the number of those interested in the above occurrence, and particularly so for two reasons, viz., my previous connection with the Brighton Works, and consequent knowledge of the arrangements, and the fact that similar results have followed the short circuit of shunt-wound dynamos installed here for traction purposes.

In the first case there were two Crompton undertype shunt-wound dynamos (belt driven by independent engines) running in parallel, each being provided with a separate belt-driven shunt-wound exciter, and a *maximum* cut-out. Short-circuits in the culvert happened frequently in wet weather, six in an hour being a not unknown number. A heavy short-circuit almost invariably resulted in both cut-outs opening and in the *demagnetising* of the field of either one or other of the dynamos and *its exciter*. These were again magnetised by connection with the sound machine.

An extra heavy short-circuit often caused, not demagnetisation, but actually *reversal* of the magnetic polarity in one or other of the machines, and, of course, its exciter. Such was the trouble experienced by these reversals that compass pole-indicators were attached to the dynamo circuits.

Digitized by Google

The more recent cases have occurred with shunt wound two-pole machines coupled direct (two tandem fashion) to a Parson's turbine. Each dynamo was in itself self-exciting, but the shunts were taken in parallel from the 'bus bars to which both armatures were connected. The dynamo circuits were provided with *minimum* cut-outs. Short circuits had the same effect in this case, with the exception that in some instances *both* machines were demagnetised or reversed. About a year ago these dynamos were compounded and the trouble to a certain extent, though not wholly, obviated. During the last six months two cases of demagnetisation have occurred with exceptionally heavy short-circuits.

Experimentally I have found that a current of 1,000 amperes taken momentarily (their normal maximum being 400) does not result in either demagnetisation or reversal.

It is somewhat difficult to suggest a remedy, except the obvious one of not having severe short-circuits. However, it is quite clear that minimum cut-outs will not act on the faulty machine, and the reason is not far to seek. The time required for their operation is appreciable, and the reversal of current in the armature circuit (assuming a short circuit and not an earth fault to have occurred) being practically instantaneous, before the cut-out has time to open it is again held up by the reversed current.

Assuming the short-circuit is to earth and that one earth connection is in the armature, the other being on the same (say, +) pole as the minimum cut-out but on the lamp side of it. When the faulty portion of the armature is under the negative brush, the leakage current will reach its maximum—its direction through the cut-out being the same as with the sound machines; when the faulty portion of the armature is under the positive brush, the leakage circuit will be parallel to the cut-out branch. It is scarcely probable that the current in the cut-out branch, considering its low resistance, will be rendered inappreciable by being paralleled with the earth circuit; but even were this so, its period of current reduction, with dynamos running at 300 revolutions per minute, would be so short as to render the release of the minimum cut-out impossible.

What we do find under these circumstances is that we have a pulsating current unidirectional with the normal current, and of a frequency equal to the revolutions of the dynamo. The current has *not reversed* in the cut-out branch, nor is it probable that it fell to the minimum necessary, even under normal conditions, for the release of the cut-out.

If we next consider a case in which the earth connection external to the armature is on the opposite (say, −) pole to that to which the minimum cut-out is attached, we shall see that the results are not greatly different. When the armature earth is in contact with the positive brush the leakage current will reach its maximum, but, with a low-resistance fault, the circuit of the damaged armature is completed *viâ* earth, and not through the cut-out branch. In this branch there will be a reversed current from the 'bus bar to the + armature fault. Therefore, with this arrangement of faults we get an alternating, but not necessarily symmetrical, current in the cut-out branch, of a frequency equal to the revolutions of the faulty dynamo.

The only possible conclusion we can arrive at is that minimum cut-outs (or, for the matter of that, maximum, or maximum and minimum) are not calculated to act beneficially in practice as armature protectors. As regards the non-return or reversing cut-out, it would seem that, with faults external to the armature and between it and the cut-out, we might reasonably expect this cut-out to act, but not so with faults giving rise to pulsating or alternating currents, especially when generated by high-speed dynamos.—Yours, &c.,

Electricity Works, Blackpool, Nov. 28, 1898. ROBT. C. QUIN.

THE FINANCE OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: No doubt, as you remark, the most interesting portion of Prof. Forbes' Paper, on "Long Distance Transmission of Electric Power," was that relating to the financial proposal, in which he proposes to raise the capital for the conductor by mortgage debentures. Now this proposal was first prepared and supported by an elaborate argument by Mr. B. H. Thwaite in his Paper on "The Electrical Transmission of Power from the Coal Fields." This Paper was read in November, 1892, before the Manchester Association of Engineers, and anyone interested might refer to the particular article, "The Financial Risk Involved in Laying Down Long Lengths of Electric Conductors," which contains the following paragraph:—

"This rate, $3\frac{3}{10}$ per cent., the author proposes, would be a fair rate of interest for the class of security represented by large weights of copper conductors. The author further ventures to suggest that this part of the capital, or the part to cover the cost of trunk transmission lines, should be obtained by the special issue of mortgage debentures at the rate of interest ($3\frac{3}{10}$) stipulated. *Verb sap.*"

The Paper has amongst its illustrations a graphic diagram showing the line of average value of copper (Chilian) for 13 years.—Yours, &c., HORACE ALLEN.

LEGAL INTELLIGENCE.

Williamson and Joseph v. Lawrence and Butcher.

In the Lord Mayor's Court (London) on Monday, plaintiffs sued to recover £11. 14s. 5d. for electrical fittings supplied. Defendants raised a counterclaim in respect of alleged defective materials. Mr. Robert Fisher, secretary to the plaintiffs, said their terms were monthly account, and their pay day was the first of the month. He had applied to the defendants for payment of the account on several occasions, and on the last occasion some complaint was made as to certain lamp holders being defective. These goods had been delivered two months before any complaint was made. Mr. John Hart, plaintiffs' manager, said that no complaint was received from defendants as to the fittings supplied until they were pressed for payment. For the defence, Mr. Lawrence, a member of defendant firm (electric light contractors, Stafford-street, London, W.), said that the four dozen lamp holders used in a contract they were carrying out were defective, the faults being discovered in September. The holders were sent direct to the job and had not been tested before being sent out. He had been waiting to receive a detailed statement from plaintiffs, and within two days after that was received the present action was brought. He had tendered £8. 2s. 5d., being the amount of the account less a sum he claimed as damages for the defective lamp holders. The jury found a verdict for plaintiffs for this amount, and for defendants on the counterclaim for £1. 10s., defendants to return the goods alleged to be defective.

Holliday v. National Telephone Co. (Limited).

Mr. Justice Wills and Mr. Justice Lawrence on Tuesday delivered judgment in this case, an appeal by the company from the decision of the Deputy Judge of the City of London Court, who had entered judgment for plaintiff for £25 under the following circumstances:—The defendant company were laying down telephone wires at the Pavement, Clapham, and entered into an arrangement with a plumber named Highmore, who contracted to do soldering work at so much per joint. The work of soldering had to be performed to the satisfaction of the defendants' foreman. While Highmore was attending to the soldering metal the benzoline lamp used exploded through a defective valve. The molten metal flew about, and some struck plaintiff, who was passing, causing the personal injuries in respect of which he brought the action against the company. Plaintiff alleged negligence on Highmore's part in using a defective lamp, and that as Highmore was the servant of defendants they were liable to pay compensation. The Court now held that Highmore was in no sense a servant of the company, but a master plumber who was in the habit of accepting contracts of this nature. The Deputy Judge was wrong, and the appeal was therefore allowed and judgment entered for the defendant company with costs.

National Telephone Co. v. Commissioners of Inland Revenue.

The appeal of the National Telephone Co. from the decision of Mr. Justice Grantham and Mr. Justice Channell, on Dec. 14 last, will be heard in the Appeal Court I., before Lords Justices A. L. Smith, Rigby and Collins, on Dec. 8.

Morley Electric Co. v. Briscoe.

At Blackburn County Court last week the plaintiffs sued Mr. C. T. Briscoe, electrical engineer, Blackburn, for £45, price of a dynamo. A counter-claim was made for £36. 12s. It was alleged that the dynamo, which had been supplied by the Company to the defendant for a customer, did not work satisfactorily. It was sent to Leeds to be put right, but subsequently further complaints were made about the machine, and ultimately the Company, after much correspondence, sued for the agreed price. It was urged by plaintiffs that the dynamo was made according to the specification. After hearing evidence, Judge Coventry found for plaintiffs on both claim and counter-claim.

Electric Exploitation Company (Limited) (petition of Sussman Electric Miners' Lamp, Limited).

This case came before Mr. Justice Wright. Counsel for the company stated that it was a petition brought by creditors, but it had been arranged with their consent that there should be an adjournment for three months, as negotiations were pending which it was hoped would result in the company paying the creditor's debt.

His LORDSHIP allowed the petition to stand over for three months, intimating that the other creditors should have notice of the petition.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November 18.*

Electric Railways in New York City.—Until as late a time as two or three years ago horse-power has been depended on entirely in New York for moving the cars on various street railway lines, while in other cities, even to the smallest, the overhead trolley has been introduced with uniform success and satisfaction. There was a good reason, however, why like improvements were not introduced in this city, for the city ordinances forbade the erection of overhead wires of any description within the city limits. The day came, however, when a satisfactory underground system made its appearance, and the railway companies of this city were not slow to perceive its advantages. As has been pointed out in past correspondence the Metropolitan Street Railway Co. is operating many of its lines on the underground-conduit, open-slot system, and the remainder of its lines are now being equipped in a like manner. All of the street railways in this city are controlled and operated by two companies, the Metropolitan Street Railway Co. and the Third Avenue Railroad Co. The principal lines of the latter have for several years past been operated by cable power, but the limit of capacity of this system having been reached the Company has decided to abandon it and substitute therefor the underground conduit system on all of its lines, some of which are at the present time operated by animal power. Last week the Company commenced the work of introducing the electric system on its two main lines—the Third Avenue-road and the 125th-street line, the latter of which is located in the upper part of the city. The system so laid down will be similar to that used by the Metropolitan Street Railway Co., which is known as the General Electric Co.'s system. On the Third Avenue-road the old cable conduits will be utilised for the electric system, but new 7in. girder rails will be laid. On the rest of the lines entirely new construction will be placed. One noticeable feature of this work, both as regards the Third Avenue improvements and those of the Metropolitan Street Railway Co., is the large number of ducts laid underground alongside of the conduits—a great many more than the Companies have use for. A new company, the New York Gas, Electric Light, Heat and Power Company, has been recently organised with a capital of £5,000,000, but up to the present time it has been impossible to ascertain its object. Various rumours have been in circulation to the effect that its purpose was to buy up or otherwise obtain control of all of the electric lighting interests in Greater New York and conduct the electric light and power business under one management. It is now stated that this concern will rent the ducts not needed by the railroad companies to the subway company, which controls all of the underground conduits in the city.

A Recent Patent of Nikola Tesla.—The daily papers within the past week, by means of startling headlines, announced that Mr. Nikola Tesla would make war so horrible that no nation would care to undertake it. The basis of the story rested on a patent issued to Mr. Tesla on November 8th. The facts, as set forth in the patent, are in brief as follows:—Hitherto the only practical means of controlling the movements of a vessel, such as a torpedo or torpedo boat, at a distance, has been by the use of a cable, the disadvantages of which are obvious. The plan proposed by the inventor is to provide any such craft with a coherer connected between the hull and an elevated terminal, and to so arrange the propelling and steering mechanism which is motor-driven with storage battery supply, that it can be controlled by various relays and auxiliary devices actuated through the agency of the Hertz waves. A single coherer is used. It possesses some elements of novelty designed to yield a more uniform decohering action. It consists of a metal cylinder, with insulating ends and a metal rod passing lengthwise through it. The cylinder normally stands with its axis vertical, and the decohering action consists in inverting it, throwing the particles, which occupy one-fifth of its length, from one end to the other. According to the patent, these granules are manufactured by a special tool, insuring their equality in size, weight and shape, and are uniformly oxidised. This secures equal conductivity of their surfaces, and stops their further deterioration, thus preventing a change in the character of the gas in the space in which they are enclosed. The auxiliary devices consist of ordinary relays, actuating a multiple step-by-step escapement wheel, which, in turn, rotates the brushes and commutators, affecting the various internal circuits of the boat.

Motor-Carriage Contest.—An interesting competition between various types of motor carriages took place at the Charles River Park, Cambridge, Mass., on the afternoon of November 9th, under the auspices of the Massachusetts Charitable Mechanic Association. Prizes to the value of £220 were offered by the management, and a large number of people witnessed the novel spectacle. In the parade were vehicles representing the electric, steam and gasoline methods of propulsion. The first event was the speed contest, a two-mile pursuit race. No electric vehicles took part in this race, which was won by the De Dion gasoline tricycle, in 5min. $1\frac{2}{5}$sec.; the Whitney steam carriage came in second. In the brake efficiency contest the Riker electric carriage, made by the Riker Electric Motor Co., of Brooklyn, took the first prize, stopping at 6ft. 1in., the Haynes gasoline carriage taking second prize. The next contest was as to manageability, and was won by the De Dion tricycle. The Riker Electric carriage, which was 4ft. 8in. wide, did some excellent work in this contest. The severest test of all was the hill-climbing contest, the Stanley steam carriage leading, followed by the Whitney steam carriage. The Riker electric carriage reached over 62ft. in the three trials, the Stanley steam carriage making but one trial on a rush, and covering a distance of 80ft. in $4\frac{3}{5}$sec.

PROJECTED LIGHT RAILWAYS.

During the past six months 54 applications have been deposited with the Light Railway Commissioners for powers to construct light railways, compared with 32 in May and 30 in November last. On the present occasion 34 of the applications are electrical against 18 in May last. Below are given interesting particulars of the electrical schemes, which no doubt will be found useful :—

Name.	Promoters.	Engineer.	Mileage.	Motive Power.	Gauge ft. in.	Estimated Cost.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free ; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated ; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net ; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 280 illustrations. Price 10s. 6d., post free ; abroad, 11s.

"WIRELESS TELEGRAPHY : SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net ; in sets of any three, 1s. net ; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net ; or in handy portfolio, price 12s. net ; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d. ; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d. ; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free ; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free ; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour ; price 7s. 6d. ; by post, 7s. 9d. ; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d. ; post free, 13s. ; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d. ; post free, 13s.

Digitized by Google

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY." By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R. Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

Extension of Time.—The *Salford* Electric Lighting committee invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Further particulars are given in an advertisement in another column, and specifications, forms of tender, &c., may be obtained from the borough electrical engineer (Mr. C. L. Turner), Walmesley-road, Broughton. Tenders, addressed to the chairman of the Electricity committee, must be delivered at the offices of the town clerk (Mr. Samuel Brown), Town Hall, Salford, *by Dec. 15, not Dec. 1, as originally advertised.*

The Corporation of *Barnsley* invite tenders for the supply and erection of: (1) Lancashire boilers and Green's economiser; (2) engines, dynamos, switchboard, condensers, feed-water pumps, balancing transformers, boosters, piping, tanks, crane, wiring of works, and engine, &c., foundations; (3) secondary batteries and accessories; (4) feeder and distributing mains (solid system); (5) potential leads, network and service boxes and service connections. Further particulars in our advertisement columns, and specifications, &c., can be obtained on application to the consulting engineer (Mr. Thos. L. Miller), 7, Tower-buildings, N., Water-street, Liverpool. The Corporation also invite tenders for the erection of a chimney and engine, dynamo and boiler house, storage rooms and offices. Specification, &c., from Mr. J. Henry Taylor, borough surveyor, to whom tenders should be sent by noon of Monday, Dec. 12th.

As will be seen from an advertisement applications are invited from electrical engineers for preparing specifications, drawings, &c., for the installation of the electric light at the new infirmary at Highgate-hill for the Guardians of St. Mary, Islington. Further information may be obtained of Mr. W. Smith, architect, 65, Chancery-lane, W.C. Applications to the new Infirmary Buildings committee, Highgate-hill Temporary Workhouse, Holloway, N., by 10 a.m., Wednesday, Dec. 7.

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Further particulars are set out in an advertisement on another page, and plans may be seen and particulars obtained on application to Messrs. John Pook and Co., 8, Jeffrey's-square, St. Mary Axe, London, E.C. Further information may be obtained on application to Mr. Charles Mayne, municipal engineer, Shanghai, whose telegraphic address is "Dynamo Shanghai." Tenders must be sent to the secretary (Mr. J. O. P. Bland), Shanghai, by noon of Friday, March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, secretary, by noon of Wednesday, March 15, 1899.

The *Buxton* District Council require tenders for the erection of electricity generating station buildings. Tenders to the clerk.

The *Beckenham* District Council invite tenders for the supply of the following electric lighting plant:—(*a*) Water-tube boilers and economiser; (*b*) steam alternators, transformers and switchboard; (*c*) pipework, feed pumps, overhead tank, feed-water heater, &c.; (*d*) arc lamps, lamp posts, &c.; (*e*) cables and street work; and (*f*) travelling crane. Tenders to Mr. F. Stevens by noon of Dec. 17.

The *Shoreditch* (London) Vestry invite tenders for the supply of six direct-current rotary transformers, with switch gear complete, three of 66 kilowatt and three of 33 kilowatt capacity. Tenders by noon of Tuesday, Dec. 13, to Mr. C. Newton Russell, Electricity Supply Department, Coronet-street, Shoreditch.

Tenders are invited by the *Board of Control, Dublin*, for the supply of the necessary plant, wiring, &c., for the electric lighting of Richmond District Lunatic Asylum. Tenders to Mr. H. Williams, Custom House, Dublin, by 10 a.m. Dec. 5.

The *Great Northern Railway Co.* invite tenders for the supply of new, and the purchase of old, stores for 12 months from Jan. 1. Tenders to Stores Committee, at the Company's offices, King's Cross, London, N., by 10 a.m. on Tuesday, Dec. 6.

The *North-Eastern Railway Co.* invite tenders for the supply of telegraph apparatus, wire and line stores during the six months ending June 30, 1899. Tenders to the secretary (Mr. C. N. Wilkinson), at York, by noon of Monday, Dec. 5.

The *Glasgow* Corporation invite tenders for supplying switchboards and instruments at the new electricity works, Port Dundas. Tenders to town clerk (Sir J. D. Marwick) by Dec. 5.

The *Dublin* United Tramways Co. invite tenders for the supply of general stores, including electrical supplies, car fittings, ironmongery, &c., for the year 1899. Tenders to the chairman of the Company, 9, Upper Sackville-street, Dublin, by 5th prox.

The Municipal Council of *Bucharest* invite tenders for the supply of electrical machinery and electrical pumping plant for the waterworks. Particulars from M. Radu, chief of Department of Studies and Construction, of Strada Mihai-Voda, Bucharest. Tenders by Jan. 10, 1899.

Tenders and plans are invited until Feb. 1, 1899, by the Municipal Authorities of *Heidelberg* for the erection and equipment of an electric lighting station. Tenders to Der Direction der Städt Gas und Wasserwerke, Heidelberg, whence particulars may be obtained for 6s.

TENDERS RECEIVED AND ACCEPTED.

The *Bury* (*Lancs.*) Corporation have accepted the tender of Messrs. Calvert and Co. for wiring the public baths.

The *Bolton* Corporation have accepted the tender of Mr. J. Booth for the construction and erection of an iron roof at the electricity works. The tender of Messrs. Musgrave and Son for the supply of foundation plates for the two new 1,000 H.P. engines has also been accepted. The contract for the new switchboard has been given to the British Thomson-Houston Co.

The *Redditch* District Council have accepted the tender of Messrs. Johnson and Phillips for the supply of two dynamos, at £1,725, to be delivered within four months.

APPOINTMENTS VACANT AND FILLED.

The District Council of Hoylake and West Kirby invite applications for the post of consulting electric engineer to the Council, in connection with the proposed electric lighting project. Applications, on or before Dec. 6, to the clerk (Mr. Roderick Williams), Council Offices, Hoylake, Cheshire. Further information is given in an advertisement elsewhere.

The Hammersmith (London) Vestry require an electrician-in-charge for their electricity supply works. Salary £2 per week. Applications to the resident engineer (Mr. G. G. Bell), 57, Fulham Palace-road, Hammersmith, by Dec. 8. See advertisement.

A competent foreman platelayer is required by the Tramways Department of Manchester Corporation. Further particulars are set out in an advertisement. Applications (addressed chairman of Tramway committee) must be sent in to the town clerk (Mr. Wm. Henry Talbot), Town Hall, Manchester, by Saturday, the 10th inst.

As announced by us last week, the London County Council have appointed Mr. John Young, manager of the Glasgow tramways, chief officer to the London County Council tramways at a salary of £1,500 per annum. Seventy applications were received for the post, out of which number there were selected: Mr. J. Young, Mr. J. Aldworth (of the Isle of Man tramways), and Mr. A. Baker.

Mr. A. Banks Johnston, who has been for ten years engaged in the consumers' department of the Chelsea Electricity Supply Co., was on Wednesday elected prime cost clerk and third assistant clerk in the electricity department of the St. Pancras Vestry.

Digitized by Google

Mr. Hanson has been appointed resident electrical engineer to the Fleetwood and District Electric Light and Power Syndicate, Limited.

BUSINESS NOTICES.

Messrs. Hodges and Todd (Limited) are now connected with the National Telephone Co.'s exchange system, No. 5115 Gerrard.

The London offices of Messrs. Ruston, Proctor and Co. have been removed to Stafford House, 27A, Cannon-street, E.C.

Mr. David Stevenson has taken offices at 17, Victoria-street, Westminster. Mr Stevenson was formerly connected with the "E.P.S." Co. and with Messrs. Drake and Gorham. He went to South Africa in 1891, and was for some years a partner in the firm of Edlin and Stevenson, of Cape Town. He will devote himself especially to electrical power distribution in factories and to electro-motor work generally.

The manager's and secretary's offices of the Western and Brazilian and the London Platino-Brazilian Telegraph Companies have been removed to Winchester House, Old Broad-street, London, E.C., where all communications should be addressed. The transfer offices of these Companies and of the Brazilian Submarine Telegraph Co. are now at Blomfield House, London-wall, E.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

The application for the discharge in bankruptcy of A. H. Crump, trading in London with S. G. Trehearne as Trehearne, Son and Crump, electrical engineers, &c., will be heard on 13th inst. at Bankruptcy Buildings, Carey-street, London, W.C.

It has been resolved to wind up the Western Canada Telephone Co. (Limited) voluntarily, and Mr. G. P. Norton, Huddersfield, has been appointed liquidator.

A second and final dividend of 2d. in the £ is announced in the matter of the London Metallurgical Co. (Limited) by the liquidator, Mr. Stewart Bogle, 91-93, Palmerston-buildings, London, E.C.

Catalogues.—Messrs. Babcock and Wilcox (Limited) have recently issued a new edition of their well-got-up catalogue, entitled "Steam." This production is really more than a catalogue, and includes a very practical treatise on steam production and the management of steam generating plant. The treatise, which is strongly bound, opens with an essay on "Economy and Safety in Steam Generation," the illustrations of which show various types and details of the Babcock-Wilcox water tube boiler, and the text of the essay takes the reader through the elements of thermo-dynamics and the theory of heat generators and engines, and also deals with two such practical matters as the best means of producing circulation and good dry steam economically. One of the best illustrations shows Babcock-Wilcox boilers installed in the electric shop at Portsmouth Dockyard working under a pressure of 350lb. to the square inch. Several illustrations of its various forms of the Babcock-Wilcox type of mechanical stoker are also shown. Messrs. Babcock and Wilcox (Limited) are doing engineers and steam users good service by offering copies of "Steam" free of cost.

Messrs. Polland and Co., of 5, St. Nicholas-buildings, Newcastle-on-Tyne, issue a useful sheet of electrical apparatus and accessories which they are importers of and agents for.

A price list and catalogue of "Svea" glow lamps reaches us from Messrs. J. C. Lyell and Co. An interesting introduction deals with the subject "How Electrical Glow Lamps are Manufactured," and is fully illustrated. The list is strong in high voltage lamps.

Messrs. A. Vandam and Co. forward a strongly-bound catalogue of electrical supplies. The catalogue is fully illustrated.

Scientific Apparatus Catalogue.—We have received from Messrs. John J. Griffin and Sons (Limited), 20-26, Sardinia-street, London, W.C., Part 3 of "Griffin's Illustrated and Descriptive Catalogue of Scientific Apparatus," for use in educational establishments. This is the eighth edition of Part 3, which is devoted to magnetism, electricity and galvanism, and comprises 180 large octavo pages, fully illustrated with every variety of apparatus for electro-technical laboratory and general experimental work. The lecturer on electricity and magnetism will find the catalogue indispensable, and the practical worker will also find his requirements catered for.

Railway Guide.—Health seekers and travellers generally will be interested in an illustrated guide and official list of hotels, boarding houses, seaside and farm house apartments, available throughout the extensive district covered by the London and South Western Railway Co. in the Thames Valley and in the south-west of England. Illustrations and text will lend additional attraction to the book, which will be published early in April next by Messrs. Spottiswoode and Co., the well-known London publishing house.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Nov. 23 to Nov. 29, with the ports of destination:—

Argentina—Buenos Ayres, £1,421. *Australasia*—Adelaide, £103 (telegraph material); Brisbane, £191 (including £101 telegraph material); Melbourne, £386 (including £364 telegraph material); Sydney, £1,097. *Belgium*—Antwerp, £35. *Brazil*—Rio Janeiro, £5,136 (telegraph material). *Canada*—Santos, £240 (including £165 telegraph material). *Ceylon*—Colombo, £105. *Chili*—Valparaiso, £1,186 (telegraph material). *China*—Shanghai, £110. *Denmark*—Copenhagen, £26. *Egypt*—Alexandria, £346 (including £150 telegraph cable). *Germany*—Hamburg, £110. *Holland*—Amsterdam, £80. *Hong Kong*—£171. *India*—Calcutta, £1,743. *Italy*—Venice, £230. *Japan*—Yokohama, £474. *Malta*—£30. *Norway*—Christiana, £280 (including £185 telegraph cable). *Russia*—Helsingfors, £20. *South Africa*—Durban, £201 (including £12 telegraph material); East London, £108; Port Elizabeth, £26. *Spain*—Malaga, £70. *Straits Settlements*—Singapore, £243. *Sweden*—Stockholm, £1,785 (including £85 telegraph material). *West Africa*—Senegal, 130 knots telegraph cable). Total, £15,962, against £8,573 in the corresponding week last year (Nov. 24 to Nov. 30).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Airdrie and Coatbridge Electric Tramways.—Having failed to obtain the sanction of the Board of Trade to the order of the Light Railway Commissioners for the construction of the Airdrie-Coatbridge electric tramway, the British Electric Traction Co. have now decided to promote a Parliamentary bill for powers to construct the line. The bill is backed by the Corporations of both Airdrie and Coatbridge.

Alleged Perjury.—John Limbrey Higgs, solicitor, Delahay-street, S.W., again appeared before Mr. Lushington at Bow-street on Tuesday, in answer to the charge of having committed wilful and corrupt perjury in the course of his examination in connection with the liquidation of the I.E.S. Accumulator Co. After evidence had been given by Mr. Ed. Mann, Mr. F. B. Harper and Mr. A. J. Schweder, the hearing was again adjourned.

Aylesbury.—A report from Mr. F. Hastings Medhurst, the Council's consulting engineer, recommending the erection of electricity supply works was discussed at a recent meeting. The total capital expenditure for a supply equivalent to 5,000 8 c.p. lamps is put at about £14,000. It has been decided to apply for a provisional order.

Brighton.—The Local Government Board have sanctioned a further loan of £56,300 for electric lighting purposes.

Costa Rica.—The main streets of San José are lighted by electricity.

The land telegraph lines of Costa Rica consist of 744 miles of lines, and there are 65 offices. Telegraph rates are very low. There is no submarine cable station nearer than San Juan del Sur in Nicaragua. There are 203 miles of telephone wires between the capital, San José and the outlying communities and plantations. The number of calls average about 2,500 daily.

Croydon.—The borough electrical engineer (Mr. T. H. Mitchell) is to report upon the question of extending the electric light mains to South Norwood.

Darwen.—The Corporation have decided to purchase the undertaking of the local tramways company for £48,500. A bill is being promoted by the Council for the construction of additional tramways, for the introduction of electric traction and for other powers. Mr. H. Graham Harris, as the Council's expert, has reported that the track is throughout suited for conversion to electric working.

Dundee.—The Town Council will apply to the Secretary of State for Scotland for power to borrow a further £50,000 for electricity supply purposes. The Tramways committee had a meeting on Wednesday to consider the most suitable form of traction for the local tramways. A communication was received from Prof. Kennedy declining the appointment of consulting engineer, and stating that the conduit system was still in a stage of experiment, and that it would be much cheaper to adopt the overhead system. The meeting concurred in this view, and decided to have plans prepared for the application of electric traction to the Perth-road tramways, and also to have a statement prepared regarding the construction of the new electrical route along Broughty Ferry-road. The preparation was entrusted to the electrical engineer (Mr. Walter H. Tittensor) and the burgh engineer, who are to submit reports as to estimated cost.

Earl's Colne (Essex).—A parish meeting has voted in favour of adopting the Lighting and Watching Acts. Electric lighting finds favour.

Educational.—Mr. E. H. Todd, a matriculated student at the South-Western Polytechnic Day College for Men, has been appointed to an open Exhibition in Physics and Chemistry, at Christ Church, Oxford, of the value of £80 per annum, tenable for four years.

Electricity "in Bulk."—The Council of the Association of Municipal Corporations have appointed a sub-committee to organise

Digitized by Google

opposition to the General Power Distributing Co.'s Bill, and all similar schemes for the supply of electricity "in bulk."

Electric Cabs.—The Commissioner of Police, in his annual report, makes the following remarks on electric cabs :—

The vehicles are roomy, the interiors well fitted and the mechanism is well under the control of the driver. Experiments are, however, being made with a view to reduce their weight, &c. Should electric carriages come generally into use, the effect on the traffic of the metropolis will be marked, as such vehicles occupy but a little over one-half the space of that of a similar vehicle drawn by a horse. From a sanitary point of view also a diminution in the number of horses in the streets is a desideratum. The one-stage carriage, propelled by electricity, has not yet been put on the streets to ply for passengers.

Electric Launches.—The Thames Valley Launch Co. (Limited) recently despatched to Colombo, Ceylon, two specially-designed launch electric motors for use in boats which are to be built in Colombo. The full electrical equipment for the launches were included in the shipment. This firm report that they are sending out to the colonies and abroad complete sets of plant for erection into hulls built abroad.

Electrical Concessions in the Turkish Empire.—An imperial iradé has now been issued by the Sultan granting to Sir Ellis Ashmead-Bartlett a concession for the establishment, with a monopoly, of electric lighting systems in the towns of Salonica and Smyrna.

Electric Traction in Germany.—According to the Berlin correspondent of the *Economist*, last year there were built 453 miles of electric railways in Germany, France, Austria, Italy and England together, and of this amount Germany constructed about two-thirds.

Glasgow.—A lengthy memorandum was presented recently to the Tramways committee of the Glasgow Corporation by Mr. John Young, general manager, who has now been appointed to the London County Council Tramways Department. The report deals with conduit and overhead systems of electric traction, and refers at the commencement to the report of the deputation from the Tramways Committee in 1896 in favour of electric working of the town tramways. The main recommendation of that report was that an experimental line on the overhead system should be tried, and the Springburn route was selected. Overhead construction was proceeded with, and rosettes were used instead of side poles, showing the overhead system, as Mr. Young thinks, at about its best. It is only within the last two or three weeks that horse cars have been entirely displaced by electric cars on the Springburn route, and the power station plant has not even yet been completed so as to be taken off the hands of the contractors. The operating figures can, therefore, hardly be taken as normal. The results of the experiment as regards efficiency and economy are, however, described as very satisfactory. For the week ending 12th November ult., the total operating expenses for the electric route were, as near as may be, 6½d. per car mile, while the receipts amounted to 1s. 4½d. Mr. Young continues: "There can be no doubt electric traction does very appreciably increase the revenue. Apart from this consideration, important as it is, financial success is assured by the fact that, during the first full week of operating our small electric installation, working only at half its power, we can show a saving on working expenses, as compared with horse traction, of 2d. per car mile." It has been for a long time past a difficulty to cope with the increasing tramway traffic in Glasgow, but Mr. Young thinks it would be unfortunate at this time of day to propose to build more stables or horse cars :—"The only relief we can otherwise have, until a general scheme for electric traction has been adopted, is to electrically equip the route in continuation of High-street from Glasgow-cross to Govanhill, and across Coplaw-street to Coplaw-hill car works. An electrical connection between the car works and the power station at Springburn is absolutely necessary at any rate. It is calculated that the engines and dynamos now in the power station can operate this extension, and, of course, better results will be shown when full advantage is taken of the power plant. The question is, should this extension be on the overhead or underground system—or, rather, should we have a demonstration of the conduit system before finally discussing a complete scheme of electric traction for the city?" After dealing fully with the statement recently published of the experience with the conduit system in New York, Mr. Young says :—"The extra cost of the conduit system of traction can be better afforded now that electric power can be produced at what a few years ago would have been looked upon as merely a nominal addition to the cost per car mile run. Further, one system for the entire city would certainly be preferable. Otherwise there would be difficulty in determining where one system should end and another begin. To convert the whole track from Glasgow Cross to Dixon Halls for overhead traction would cost about £16,000; for overhead from Glasgow Cross to Rutherglen-road, and conduit beyond, about £27,000; and for conduit throughout, from head of Saltmarket, about £33,000. The overhead lines on Coplaw-street, and in car works and sheds would be about £4,000 additional. Even a small demonstration of the conduit system on this route would mean losing a considerable time in having it electrically operated. For my part (concludes Mr. Young) I should much prefer to have the direct line from the power station to the car works operated throughout on the one system, and to have this carried out at once. If it is desired to have a demonstration of the conduit system, what I would suggest is this :—Proceed at once to equip the Govanhill route, as proposed, on the overhead system throughout, and arrange to demonstrate the conduit system on the Dennistoun route from St. Vincent-place to the terminus. The current for this demonstration could easily be supplied from the present power station, *via* High-street, and the working costs kept quite separate. The Kelvinside cars could simply turn at St. Vincent-place, as in former times, and this would completely isolate the Dennistoun route for this purpose." This recommendation having been duly considered by the Tramways committee, that body decided, on Wednesday, to equip the Glasgow Cross to Govanhill line on the overhead trolley system, and to make an experiment with the conduit system in another part of the city.

Mr. A. R. Bennett has just presented a report to the Glasgow Corporation, in which he states that the estimate prepared by him for the Glasgow telephone inquiry of £100,000 for 5,200 subscribers and call offices actually working, besides 1,200 spare unfinished lines and 587 junction lines, may still be taken as correct. It was, he says, based upon the same type and quality of material as is used by the National Company, but in practice he would not recommend such a close adherence to the National Company's working as was assumed in the estimate for the purposes of comparison. As soon as the Municipal Exchange had 2,000 or 3,000 subscribers successfully talking, which stage should be reached within twelve months, he would expect that new orders would flow in very rapidly, and that by the end of three years the orders already executed and on hand would number 10,000, or, perhaps, 12,000. He would, therefore, recommend the adoption of double the number of lines contemplated, or 10,400 completed and 2,400 spares—12,800 in all—as a basis for the initial scheme, which he estimates at £200,000, or a rental of £6. 17s. 1d. per line. He estimates, however, that all the rental necessary would be £6. 1s., instead of £5. 5s. originally proposed. This 16s. on 10,400 lines would, in twelve years, produce £99,840, which, added to the £72,000 of sinking fund, would, apart from accumulations, amount to £171,840 in 1912. Thus only £28,160 would remain to be recovered by sale to the Post Office or sale of assets. The 16s., he suggests, should be a precautionary contribution to a sinking fund which may or may not be ultimately required, and could be made returnable to the subscriber in 1912 should the licence be extended, or should sale to the Post Office or realisation of assets render the sinking fund superfluous.

The supply of electric light to many private consumers in Glasgow has had to be curtailed. No further applications for Corporation current can be granted. Notice was, some time back, given to new applicants that current could only be supplied on condition that the Corporation could cut it off when it was found necessary. There are 110 consumers of this description, and it is not expected that these will receive full supply until the beginning of the year.

Greenock.—The burgh electrical engineer (Mr. S. E. Fedden) has been requested to report as to the advisability of purchasing the tramways within the burgh area, and also as to the cost of equipping the lines electrically.

Government Purchase of the Telephone.—We recently referred to a suggestion made by Mr. Edward Rae (speaking on behalf of the provincial Stock Exchanges) for the purchase by the Government of the National Telephone Co.'s undertaking. Mr. Rae has further written to *The Times* as follows :—

As a result of my letter of the 16th inst., I have received very many communications, without exception favourable to my proposal, and as the matter is likely to come before public associations for discussion, I am desirous to place the matter, if possible, in a more definite form. I think it is not too much to say that an almost universal feeling exists in favour of nationalisation. This may be attained by one of two courses—first, the absorption, or, secondly, the extermination, of the National Company's undertaking. I venture to think that the former is not only the most just, but also the more profitable course for the country. I think, however, that, before the question can with advantage be discussed further, the National Co.'s board should in fairness make known their views to the public and state

1. Whether they are prepared to negotiate with the Government upon the terms suggested, or upon what terms; and
2. Whether they can give an assurance that the earning possibilities of the Company are not over-estimated in the outline given below.

The purchase money of the National Co.'s system on the basis advocated in my last letter—namely, the average prices of the Company's securities for the three years ending June 30 last—would amount to £6,850,000;

Digitized by Google

and this might be met either by unemployed funds in the hands of the Post Office, or by the issue of terminable annuities, or of £6,525,000 Two and a-Half per Cent. Consols at £105 per cent. The following figures, taken from the company's balance-sheets, show the gross receipts, working expenses and net receipts for the three years ended June 30, 1896, 1897 and 1898, and the average figures for the same period respectively:—

	1896.	1897.	1898.	Average.
Gross receipts.....	£853,416	... £916,931	... £1,046,468	... £938,938
Working expenses (excluding royalties.....	441,230	... 507,074	.. 581,736	... 510,013
Net receipts	£412,186	... £409,857	... £464,732	... £428,925

The sole tax upon these net receipts after a Government purchase being the interest charge, which I will take as £165,125 per annum, upon the purchase money, there would remain an average net result, inclusive of royalties, of £265,800 per annum. This annual result, excluding any allowance for the steady progressive increase in the Company's profits—namely, £31,000 per annum on the average of the three years—if placed to a sinking fund at 2½ per cent., would in the year 1911 amount to upwards of £4,000,000, or, including such progressive increase, to a sum exceeding £7,000,000, and even excluding the royalties from consideration as part of the Company's earnings, to a sum exceeding £5,500,000. I think the Post Office would be fortunate in securing the extinction of the Telephone Company's licence upon such terms.

The second course—that of harassing the National Company out of existence—can only be pursued at a serious loss to the public purse and an entire sacrifice of public convenience. I appeal to the ablest experts of the Post Office to say whether this is not so. The Company, it is to be feared, would have only too many facilities during the currency of the licence for thwarting and even paralysing the Post Office Department in their endeavour to supersede them by competition; and I repeat my belief that, of the two courses indicated, the country would prefer to seek a settlement with the National Company upon an equitable basis.

Hammersmith (London).—The number of applicants for electric current to date is 249, representing an equivalent of 19,464 8 c.p. lamps, and of these 190 (13,840 lamps) are connected.

Leatherhead.—The time for sending in tenders for taking over and working the District Council's provisional order has expired, but no tender has been submitted. The Electrical Power Distribution Co. intimate that they will establish large generating works in the neighbourhood and will be able to supply current at a lower rate than the Council itself can generate it. A committee is considering the matter.

Lectures.—The borough electrical engineer (Mr. R. C. Quin) lectured to the Blackpool Literary and Scientific Society last week on "Modern Applications of Electricity." The town clerk (Mr. T. Loftos), who presided, said that Blackpool was the first town in the kingdom to obtain statutory electric light powers, and it was satisfactory to know that the first installation was highly successful, and that the whole cost of it had been paid off. Blackpool was also a pioneer in electric traction, having been the first town to use it in England if not in the United Kingdom. Much of their success in electrical matters was due to Mr. Quin, who had had considerable experience in another well-known health resort. Mr. Quin's lecture treated of electricity as an illuminant, a cooking agent, a telephonic and telegraphic medium, in therapeutics, &c., and the lecturer was accorded a hearty vote of thanks at its termination.

Limerick.—The Town Council have decided to put their provisional order into force, and the Board of Trade have been requested to defer considering the revocation of the order until the election of the new Council.

Liverpool.—The city electrical engineer (Mr. A. Bromley Holmes) has been requested by the Tramways committee to consider and report as to the price to be charged for current supplied for lighting the tramcars.

London County Council.—At Tuesday's meeting loans of £10,490 to Hampstead Vestry for electric lighting purposes, and of £5,690 to Battersea Vestry, for extensions of the Vestry's electric lighting station, were approved.

The appointment of Mr. John Young, the popular manager of the Glasgow tramways, as chief officer of tramways at a salary of £1,500 a year (as announced in our last issue), was confirmed.

Madagascar.—Except a few French officials connected with the telegraph lines, there are no persons engaged in electrical work in Madagascar. A correspondent writing under date Oct. 31 bemoans this fact.

Manchester.—In a communication to the local press the city electrical engineer (Mr. C. H. Wordingham) states that Manchester, in common with other large towns, such as Edinburgh, &c., owning electricity supply works, is now feeling in an acute manner the effects of the dispute in the engineering trades last year. The check to production then given has caused an enormous conglomeration of work, and plant ordered is many months, and in some cases a year or more, overdue. The Electricity committee at Manchester have now on order two large generators, each of 2,500 H.P., and capable of supplying together 100,000 lamps. One of these was guaranteed to be running by October, 1897, the second by September, 1898, and neither of these is yet at work. In spite, therefore, of the foresight of the committee in ordering plant well ahead of the probable demand, they had no more plant capacity than in March, 1897, and the consequences were now being felt by their consumers. Further than this, 10 additional boilers, equivalent in steam-raising capacity to the number now fixed, are also much overdue, and they were thus doubly handicapped. For the last two evenings the pressure on the electric mains was as low as 87 volts on Monday for about an hour, and on Tuesday for about two hours. Everything that was possible to be done had been and was being done. The boilers were being forced to a very large extent, and the whole of the existing plant was greatly overloaded. It might be said that, having in view the inadequacy of the plant, new connections ought not to have been made. Consumers would remember that last winter the connection of new lamps was completely stopped from November, 1897, to February, 1898. Relying on the promises of contractors to complete their work, it appeared perfectly safe to take off this prohibition last spring, and the committee could not have foreseen that there could have been such an utter failure on the part of the manufacturers. Mr. Wordingham is confident that in about a fortnight they would have six new boilers and one of the new generators at work, and in the meantime he asks consumers to bear with the low pressure with as much patience as possible, remembering that every effort is being made on the part of the Electricity committee.

Manchester Improvements.—A deputation waited on Sir Courtenay Boyle, at the Board of Trade last week, to lay before him details of the Corporation's tramways bill. This bill gives Manchester power to lease lines from the Corporations of Salford, Oldham, Stockport, Ashton-under-Lyne, Stalybridge and Eccles, the District Council of Swinton and Pendlebury, and the urban districts between these places and Manchester, and to work them as one system. Authority is sought to utilise different kinds of motive power—electricity, oil, gas, steam, &c. The Corporation seeks a provision for the "postponement of payments to any sinking fund formed for the discharge of moneys borrowed or raised under the intended act, and for the payment of preliminary expenses and interest out of capital, for such period as may be prescribed by the intended act, or sanctioned by some public authority, and to make other provision in regard to the repayment of borrowed money." As it will be some time before the Corporation can obtain possession of the lines, and considerable expense must necessarily be incurred in the laying down of electric plant, purchase of cars, &c., the Corporation do not desire to burden the rates with any of these charges, and consequently wish, until the tramways begin to show an earning capacity for the Corporation, to pay interest and sinking fund charges out of capital. It will be seen that the Corporation wish for such powers as have as yet been granted to no other municipal body in the kingdom.

Niagara Power Co.'s Undertaking.—It is alleged that the Niagara Power Co. have broken the conditions of the agreement under which it was granted its lease. An agreement was made in May, 1892, with the Ontario Government and confirmed by 55 Vic, chap. 8. for the right to take the waters of the Niagara River in Queen Victoria Niagara Falls Park, for which an annual payment of $25,000 per annum for ten years was to be made by the company. The company was required to commence work before May 1, 1897, and to proceed at such speed that water connections for 25,000 H.P. would be completed and 10,000 H.P. ready for supply by Nov. 1, 1897. The company has, it is alleged, failed to carry out this part of its agreement, and the Governor in Council, acting under advice of the Attorney-General, has submitted to the High Court the following points:—(1) Is the agreement void by reason of the failure of the company to carry out its agreement with reference to the development of power? (2) May it be declared void? and (3) If the agreement with the company is not at an end, are the Government or Commissioners of the Park empowered to grant the right to take and use the waters of the Niagara River within the limits of the park?

Rangoon.—Mr. R. Hammond's report upon the establishment of electricity supply works has been submitted to the Municipal Council. Mr. Hammond recommends the laying of mains in the whole of the municipal area, and the total capital outlay involved is estimated at 1,267,367 rupees. The municipal engineer (Mr. Stirrat), however, advises the Council to commence by laying down a small plant, but to make provision for extensions. No decision has yet been come to.

Perth.—The station, shunting yard, &c., are to be lighted electrically. An independent steam plant is to be put down.

Redditch.—At a special meeting of the District Council, held to authorise the acceptance of a fresh tender for the supply of

Digitized by Google

dynamos for their electricity works, it was stated that the original contractors (the United Ordnance and Engineering Co.) had gone into liquidation. Correspondence had taken place between their electrical engineer (Mr. McMullen) and the official receiver of the Company, who proposed to carry out the contract at an addition of £200 to the sum originally mentioned, and the committee were prepared to accept the contract at the increased price of £1,638, but as it transpired that the official receiver was not prepared to guarantee any time for delivery, a fresh tender was accepted from Messrs. Johnson and Phillips. (*See* under "Tenders Accepted.")

Speed of Electric Tram Cars.—At Dublin, last week, Sir F. Marindin concluded his inquiry into the application of the Dublin United Tramways Co. for permission to increase the speed of the electric cars between Dublin and Dalkey, *via* Blackrock and Kingston. A mass of evidence was given by residents and others in favour of the application, but opposition was made by the Car Owners' Association and the Dublin and Wicklow Railway Co.

St. Pancras.—At Wednesday's meeting of the Vestry, Dr. Walter Smith moved the report of the Electricity and Public Lighting Committee. The report recommended that the salary of Mr. A. E. Pycraft, chief clerk of the department, should be increased to £300 per annum. Dr. Smith said Mr. Pycraft thoroughly deserved the increase, but an amendment by Mr. Durant that the matter be referred to the Officers committee was adopted by 50 to 12 votes.

Stoke Newington (London).—The Vestry has been asked by the North Hackney Tradesmen's Association to request the Hackney Vestry when laying electric light mains on the east side of High-street to extend them to the west side, for the convenience of Stoke Newington ratepayers.

Telephone Municipalisation.—The Edinburgh Town Council have rescinded their recent resolution in favour of applying for parliamentary powers to establish and work a municipal telephone exchange.

At a meeting of the Common Council yesterday (Thursday) afternoon, Mr. Turner, in reply to Mr. A. C. Morton, said that the Corporation were about to call a conference at the Guildhall of the London Vestries and Local Authorities on the telephone question, and he hoped useful results would follow.

Twickenham.—Now that the Twickenham and Teddington Electric Supply Co. has decided to proceed with its application for a provisional order, the Joint Lighting committee of Twickenham and Teddington have decided upon a course of procedure. The Twickenham Council have unanimously adopted the report of the committee "that in the event of a favourable reply being received from the Board of Trade it is advisable that steps be taken to obtain a joint provisional order for Twickenham and Teddington with a view to proceeding with the electric lighting of the two parishes at an early date."

Walthamstow.—A Local Government Board inquiry has been held into the application of the District Council to borrow £36,490 for the erection of electricity supply works. The clerk (Mr. Gower), who appeared in support of the application, said that a provisional order was obtained in 1895, and there was no doubt a considerable demand for electric current in the district. Mr. J. Enright, the consulting engineer, submitted technical details.

Whitechapel (London).—The District Board of Works have applied to the London County Council for a loan of £25,000 for purchase of land in Osborn-street for a supply station and for the enlargement of the destructor works. Mr. Arthur Wright's report on the electric lighting is now under consideration by the Electric Lighting committee.

Whitehaven.—A Local Government Board inquiry has been held into the application of the Town Council to borrow £12,000 for electric lighting extensions. The Mayor (Mr. J. R. Musgrave) stated that additional electric lighting plant was absolutely necessary to meet the great demand. In 1894 the number of units consumed for public and private lighting was 158,201, and the equivalent number of 8 c.p. lamps was 2,962. In 1897 the figures were 184,176 and 6,081. The present plant was equal to the supply of 6,600 lamps, and they intended to put down additional plant equal to a total capacity of 10,800 lamps. There was no opposition.

Windsor.—The Town Council have decided to light three of the principal streets electrically.

Winsford.—A report from Mr. Wm. Beckett, of Manchester, recommending the erection of electricity supply works, has been discussed by the District Council. The initial cost of a smaller installation is put at £7,700, but a complete scheme for the district is estimated at £12,000. The Council will apply for a provisional order.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. 18,975. TAYLOR. Electric high and low-tension fuse head for blasting, mining and the like purposes.

COMPANIES' MEETINGS AND REPORTS.

British Electric Traction Company (Limited).

An extraordinary general meeting of the members of this Company was held yesterday (Thursday), at Donington House, Norfolk-street, London, W.C., under the presidency of Sir CHARLES RIVERS WILSON, G.C.M.G., C.B.

The SECRETARY (Mr. Geo. Stevens) read the notice convening the meeting.

The CHAIRMAN said: We have called you together to meet the requirements of the Light Railways Act, which in this respect follows the procedure of the ordinary Railways Acts in requiring that the approval of the shareholders should be signified to any applications to Parliament, and for this purpose a special meeting (called a Wharncliffe meeting) must be called. We are met to pass a series of resolutions approving the drafts of several Light Railway Orders which are in process of being promoted by the Company; these are the Light Railway Orders for Merthyr Tydvil, Kinver, Poole and district, South Staffordshire, Doncaster and district, Barnsley and district, Middleton extensions, Colchester, Spen Valley, and Dudley and district (extension). We believe this Merthyr undertaking will be a very satisfactory one, as we not only propose to carry out a light railway or tramway scheme, but to combine with it the business of supplying electricity for lighting and other purposes, and the local authorities have already approved our scheme. The Kinver Order is for an extension of the large scheme of tramways and light railways, which we have been working up in the South Staffordshire district. We are amalgamating a number of tramways which have been working by steam or horse power, and we are making extensions and junctions, and propose to work the whole of the undertakings by electricity on a uniform system, to the great benefit of the districts, and we believe to the benefit of the shareholders in this Company. The Kinver extension will, we think, be especially appreciated because it will extend the tramways of South Staffordshire. The Poole and District Order has also already been approved by the Light Railway Commissioners. The South Staffordshire Order is for making extensions in connection with the scheme I have already referred to. The Doncaster, Barnsley, Colchester and Spen Valley projects are new schemes, which we hope to be able to carry through. The Middleton Order is an extension of that Middleton Order which we have already secured. The Dudley and District Order is for an extension of a light railway which has already been sanctioned by the Board of Trade. The Directors are satisfied that all these Orders, if secured, will bring good business to the Company. As it will probably be three months before the accounts for the year and the General Report of the Directors will be in your hands, I may (although there can be no other business transacted at this meeting than that of which notice has been given) be permitted to say that the general position of the Company is highly satisfactory. The business which the Company is developing is a very large one, and I believe that, when the accounts and Report for the year are before you, you will have every reason to be satisfied with the progress we have made. With regard to profits, as the accounts for the year will not be made up until after the end of December, I cannot yet put any very definite figures before you. I have no doubt that the Directors will be in a position to recommend the payment of a dividend, but you must excuse me if I do not at present indicate what that dividend is likely to be. We are building up a very extensive business, which will require from time to time large amounts of capital; in fact, the larger the capital judiciously expended in the business, the better the results will be for the original shareholders. But in order to carry out this policy, it is important that we should strengthen the position of the Company so that there may be the fullest security for the Debenture holders and Preference shareholders, and the Directors feel that in the best interests of the Company we should work for this object instead of striving to make the largest possible distributions in the form of dividends. Turning to another subject, I need not say that a company working up so extensive and complicated a business has necessarily had many difficulties to overcome. Our negotiations with local authorities have in some instances given us cause for disappointment, and the delays in completing some of our undertakings have been greater than we would like; but on the whole, as I have stated, we have cause to be satisfied with the progress which has been made. I have mentioned to you to-day a certain number of undertakings for which we are asking for powers, but although these are numerous, they are in addition to a very large number of schemes which have already been mentioned to you, and which are already in progress. I will now ask you to express your approval of the resolutions which have been read to you.

Resolutions approving the proposed applications for Orders for Merthyr Tydvil, Kinver, Poole and district, South Staffordshire, Doncaster and district, Barnsley and district, Middleton, Colchester, Spen Valley and Dudley and district were then put to the meeting *seriatim* and approved unanimously.

A SHAREHOLDER: Are there any competitors in this kind of business?

The CHAIRMAN: Yes; there is great competition, but if it were not for this unfortunate disposition on the part of the local authorities to municipalise there would be room for all. Unless municipalities obtain special powers they cannot go outside their own boundaries, but there has been a disposition—at least, on the part of one corporation—to go outside their boundaries. There is that disadvantage we shall have to cope with.

Mr. GARCKE: There will be several Bills before the next session of Parliament which will formally raise the question.

The proceedings then terminated.

London Electrical Cab Co. (Limited).

The Directors of this company have issued their report and accounts for the period from Aug. 20, 1897, to July 31, 1898. The report is as follows:—

The Directors regret the profit and loss account shows a debit balance of £6,207. 15s. 6d. Although the company was incorporated on Nov. 12, 1896, they were unable to run any cabs at all until Aug. 20, 1897, and so were without any means of earning profit, and since the latter date only a very limited number have been on the streets, whereas the whole of the standing charges have continued during that time. The cost of purchasing electricity proved so excessive that the Directors decided to lay down a complete manufacturing plant; this plant is now working, and enormously reduces the cost of electric current. The maintenance of the accumulators and the cost of renewals of rubber tyres have also caused much anxiety and expense, but different arrangements are on the point of being completed which will place these matters on a much more satisfactory basis. The Directors purpose shortly making an issue of £12,000 in Five per Cent. Debentures, which (together with the final call on the recent issue) will, it is believed, be ample to pay all liabilities after the premises, new plant, stock, &c., have been put in thorough working order, and also to provide sufficient working capital.

At the meeting of shareholders on Dec. 5 the chairman will speak very fully as to the past, present and future workings of the business; also as to the policy of the Directors and the position of the company generally; and the works will be open to the inspection of shareholders after the meeting.

NEW COMPANIES, STATUTORY RETURNS, &c.

W. C. BERSEY AND CO. (LIMITED).—This company was registered on Nov. 28 with a capital of £5,000, in £1 shares, to acquire as a going concern the business now carried on by Walter C. Bersey, George E. Thompson, and Charles G. W. Bromfield at 39, Victoria-street, Westminster, and to carry on the business of consulting, mechanical, electrical and general engineers, suppliers of electricity, &c. The first subscribers are: Walter C. Bersey (consulting engineer), G. E. Thompson, C. G. T. Bromfield (engineer), C. Davis, L. H. Hoile, W. J. Wood and Frederick T. Bersey The first Directors are: Walter C. Bersey, G. E. Thompson, Charles G. T. Bromfield and Charles Davis.

NEW ELECTRO-CHEMICAL MANUFACTURERS' ASSOCIATION (LIMITED).—This company was registered on Nov. 22 with a capital of £2,000, in £1 shares, to carry on the business of electricians, electrical, mechanical, metallurgical and chemical engineers, suppliers of electricity, electro-platers, chemical manufacturers, &c. The first subscribers (each with one share) are: Miss E. M. Linstead, A. T. Poole, Miss F. E. Hester, G. H. Humphreys, L. Schramm (electrical engineer), J. Phillips (electrician), and H. E. Matthews.

SOUTH AMERICAN ELECTRIC CO. LIMITED.—This company was registered on Nov. 23 with a capital of £100,000, in £10 shares, to enter into an agreement with the General Electric Co. (U.S.A.) and Charles Bright, to promote and facilitate the development of undertakings for electric lighting, electric power supply, electric communication, and other industrial purposes connected with electricity, and to undertake and carry on mercantile, commercial, trading and financial business of all kinds. The first subscribers (each with one share) are: Charles Bright (engineer), C. H. Bennett, J. Oliver, R. G. Fudge, S. C. Lewis, J. J. Scott, and T. Large.

UNGARISCHE ACCUMULATOREN GESELLSCHAFT.—This company has been formed in Budapest, with a capital of 1,000,000 kroner (about £330,000), for the purpose of acquiring the rights of the Julien accumulator.

Digitized by Google

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return to Sept. 26, has been filed. The capital is £660,000, divided into 180,000 Ordinary and 150,000 Preference shares of £2 each. 90,000 of each class have been taken up, and the full amount called.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The statutory return, to Oct. 12, has been filed. The capital is £200,000, divided into 20,000 Preference and 20,000 Ordinary shares of £5 each. All of these have been taken up, and 6,600 of each class have been issued as fully paid. £3 per share has been called on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27 7/16d. per oz. (Dec. 1). Consols (2¾ per cent.) 110—110¼ for money, 110¼—110⅜ for account; 2½ per cent. 104⅛—105⅛ (Dec. 1), Stock Exchange Settling Days: Stocks and Shares Continuation Days, Dec. 13 and 28; Ticket Days, Dec. 14 and 29; Pay Days, Dec. 15 and 30; Mining Share Carry-over Days, Dec. 12 and 27.

COMPAGNIE CENTRALE D'ELECTRICITE DE MOSCOU.—This company proposes to increase its capital from 1½ million to 10 million francs, in order to establish electricity works in various towns in Russia. The new capital will be subscribed in Paris and Brussels.

DOULTON AND CO.—It is reported that the famous pottery business of Messrs. Doulton and Co. is about to be turned into a limited liability company. The death of Sir Henry Doulton involved the withdrawal of portion of the capital, and hence the flotation. The capital of the new concern is said to be £1,100,000; but only Debentures and Preference shares will be offered to the public, Mr. Henry Doulton taking the £400,000 ordinary shares in part payment of the purchase price. The business was established nearly a century ago, and the firm have extensive works and office premises on the Albert Embankment, London, and at Rowley Regis, Burslem, St. Helens, Birmingham and Paris.

ELECTRIC AND GENERAL INVESTMENT CO. (LIMITED).—The Directors of this company have declared an interim dividend of 10 per cent. on the capital paid up on the Ordinary shares, being 2s. per share, less tax. The dividend is for the six months to Nov. 30, and is payable on the 15th inst.

ELECTRIC CONSTRUCTION CO. (LIMITED).—A drawing of the Six per Cent. Second Mortgage Debenntres of this company, to be paid on Jan. 1, will take place at the offices of the Electric and General Investment Co., 1 and 2, Great Winchester-street, E.C., on Dec. 5.

ELECTRICITY SUPPLY CO. FOR SPAIN (LIMITED).—The remaining 100 5 per cent. prior lien bonds of £100 each of this Company will be paid off at par at College Hill-chambers, E.C., on and after Jan. 1.

HOWELL'S SIMPLEX ANTI-INDUCTIVE TELEPHONE SYNDICATE (LIMITED).—A meeting (statutory) of this company was held on Tuesday, at 55, Bishopsgate-street, E.C. The proceedings were private.

STOCK EXCHANGE NOTICE.—Application has been made to the Stock Exchange committee to allow the further issue of £414,526 sterling Four per cent. 500 Year Debenture stock of the Commercial Cable Co. to be quoted in the official list.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Nov. 25 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £3,140.

WESTERN UNION TELEGRAPH CO.—The annual report of the president of this company for the year ended June 30 last, presented at the annual meeting of stockholders on Oct. 12, 1898, states that the capital stock outstanding is $97,370,000.00, of which $28,850.35 belongs to and is in the treasury of the company, thus showing no change during the year. The bonded debt at the close of the year was as follows:—

Bonds due Mar. 1, 1900, 6 per cent.	$771,282 00
Bonds due May 1, 1900, 7 per cent.	4,920,000 00
Bonds due May 1, 1902, 7 per cent.	1,163,000 00
Bonds due Jan. 1, 1938, 5 per cent.	8,502,000 00
	$15,356,282 00
Less balance of sinking funds appropriations	497,406 48
	$14,858,875 52

During the year £2,000 sterling bonds (due March 1, 1900) were redeemed, and $14,000 of 5 per cent. collateral trust bonds (due Jan. 1, 1938) were issued in exchange for capital stock of the Gold and Stock Telegraph Co., upon which interest was being paid at the rate of 6 per cent. per annum. The total expenses for the year under review were $17,825,581.52. The surplus on July 1, 1897, was $7,647,541.06, and the profits to June 30, 1898, were (after deducting expenses as above) $6,090,151.26, a total of $13,737,692.32; from which there was applied for dividends $4,867,911.25, interest on bonds $896,554.95, sinking funds appropriations $9,991.00 (equal $5,774,457.20), leaving a surplus on June 30, 1898, of $7,963,235.12. There was a decrease during the year of 767 miles of poles, and an increase of 33,418 miles of wire, and of 441 offices. The number of messages transmitted was 4,022,065 more, and the revenue was $1,276,873.62 more than for the preceding year. The amount paid for taxes was $123,980.47 less, because of the settlement during the preceding year of disputed accounts with several States, but was still $144,033.50 more than was paid during the fiscal year 1896. The net increase in expenses for the year was $918,925.49. The average tolls received were 30.1c. per message, the average cost per message 24.7c. The decrease in the average tolls received, and the increase in the average cost per message, are accounted for by the large number of government and press messages, conseqnent upon the war with Spain, transmitted during the latter part of the fiscal year, on both of which classes of messages the tolls are the lowest, although the highest grade of operating service has to be employed for their efficient transmission. The surplus account was increased $315,694.06.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The transfer books of this company are closed until the 14th inst.

NOTES.

UNDERTAKERS of electrical supply are liable to pay a penalty of £5 daily for a breach of the Board of Trade regulations for constant supply and constant pressure. Under these regulations the pressure may only vary 2 per cent. from the standard when the supply is at high pressure, and 3 per cent. in other cases, and interruptions of the constant supply are only permissible for testing purposes "or for any other purposes connected with the efficient working of the undertaking." No penalty is to be inflicted, however, if the default is caused by an unavoidable accident. In the hearing of the summons brought against the Dublin Corporation on Thursday, last week, a full account of which will be found in another column, it was contended that the Corporation was liable to a penalty for failing to supply electrical energy to two consumers. This was regarded as a test case, for, during the replacement of the faulty rubber cable in Dublin, similar interruptions have been of frequent occurrence. Undertakers in a like predicament will welcome Mr. SWIFTE's decision that the interruption might be considered an unavoidable accident.

DURING the last few weeks the supply stations at Edinburgh and Manchester have been so overloaded that the pressure at the hours of maximum load has been extremely low—at Manchester as low as 87 volts sometimes. In both cases the prime cause has been the failure of contractors to deliver plant which has long been overdue. The non-delivery of plant and machinery at the contract time has of late been of frequent occurrence in the electrical engineering industry—so much so, in fact, that it has ceased to be regarded as anything unusual. A point has been reached, however, when companies or local authorities who are ordering electrical plant, whether it be for new stations or for extensions, should protest in the way most likely to have an effect on the contractors, viz., by the rigid enforcement of penalty clauses. One of the machines which should have been running in Manchester by October, 1897, is not yet at work, and it is hardly conceivable that the engineering strike can be alone responsible for this delay. But even if the delay is pardonable on account of the long cessation of work in the engineering trade, what is not pardonable is the repeated promise of early delivery by the contractors which has induced the station engineers to add to their lamp connections during the early part of the year. The latter gentlemen have now had it brought home to them that the non-reliance on the contractors' assurances, and the refusal to connect new consumers until the new plant was in position and the date of its operation certain, would not have done them a hundredth part of the damage which they have incurred through the actual course of events. Incidentally it would be interesting to know whether the supply authorities are exempt (on account of the engineering strike) from the penalties cited above.

A DELAY is taking place in the erection of the new generating station at Port-Dundas, near Glasgow, and the Glasgow Corporation has not only ceased to connect new consumers but has, we believe, discontinued the supply to some 110 who were only connected on the understanding that they should be cut off if it were found necessary. Could not a few large consumers be found in Edinburgh and Manchester willing to make a similar sacrifice? Probably they are now obliged to resort to other illuminants than electric light during some hours of the day, for electric lamps burning at 10 per cent. or more below their normal voltage will give but a small fraction of their normal light, so that the sacrifice, as things are at present, would not be very great. Doubtless the central stations themselves are not illuminated by electricity during this crisis; the various corporation offices should also be employing gas, candles or oil lamps for the benefit of the community, and surely in Edinburgh temporary arrangements could be devised to diminish the street lighting somewhat

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Stratified Brush Discharge.—Let a spark gap and a large liquid resistance be inserted in the circuit of a 60-plate Toepler machine, and let the capacity of the conductors be small. Then, according to M. Toepler, the following phenomena are observed on increasing the current strength: While the current is feeble the discharge takes the form of the ordinary brush discharge; but when the current strength attains a certain minimum limit the brush discharge is displaced by a stream of sparks. Instead of the low humming, a rattling sound is heard, rising in pitch as the current increases. On reaching a certain higher limit a nearly continuous brush light arc takes the place of the spark discharge, characterised by a great evolution of heat and by a stratification resembling that already described by the author in the case of a large battery of Leyden jars. This brush light arc burns nearly noiselessly. A further increase in the current strength does not produce any further change. On gradually reducing the current the same phenomena are noticed in the reverse order. Experiments with various gaps show that the lower limit between brush and spark discharge is nearly independent of the size of the gap, but when the current falls below a certain small minimum value none but spark discharges can be produced, however large or small the gap. If the anode is pointed the brush light arc consists of bright, whitish-violet cathode light, a second layer of brick-red light, scarlet positive light, and anode glow light. This observation is another bridge across the gulf that divides the phenomena of electric discharge in the open air and in a vacuum respectively. The analogy between the two kinds of discharge is strengthened by the fact that the Wiedemann-Hittorf law for vacuum discharges, according to which the difference of potential at which discharge sets in is independent of the current strength, also holds for these open-air discharges.

[Toepler, *Wied. Ann.*, No. 12, 1898.]

Mechanical Reproduction of Magnetic Phenomena.—C. Weyher uses a wooden shaft with strong paper paddles along its whole length to represent a bar magnet. When maintained in rotation, the shaft with its paddles represents a kind of centrifugal pump which sucks in air or water at both ends and expels it from the central region. Its rotation produces vortices in the surrounding medium, possessing a right-handed screw motion on one side of the centre of the shaft, and a left-handed screw motion on the other side. Two such models are suspended side by side by means of a cardan link, which allows them to oscillate like a pendulum, while preserving their freedom of rotation. When unlike "poles" are placed in juxtaposition, the models attract each other. When the two rotations are in the same direction they repel each other. The body exposed to the action of the magnetic model is a mill wheel capable of turning on a fixed spindle, and also of travelling along it. When it does not turn it is neither attracted nor repelled, and thus represents a non-magnetic substance. When it turns it travels along the spindle towards the "magnet." Several such mill wheels can be mounted on the same spindle, and made to represent a chain of nails adhering to a magnet. No attraction is exerted by the central region of the model magnet. The behaviour is the same in water as in air, but the rotations can be slower in water.

[Weyher, *Comptes Rendus*, Nov. 21, 1898.]

Secular Variation of Magnetic Elements.—At the British Association meeting, A. Schmidt, of Gotha, suggested a new use for the various navies of the sea-faring Powers, which which would be of great benefit to magnetic science. These navies, particularly the British navy, visit annually a large number of out-of-the-way places, widely dispersed over the globe, where no magnetic observatories exist. The officers have already sometimes carried out valuable magnetic surveys, and the American naval men have done useful work in this direction. Dr. Schmidt suggests that some method should be introduced into the work, thereby forwarding magnetic exploration and increasing the usefulness of our "bloated armaments." If a certain number of selected "secular stations" were visited, say, every five years, that would suffice for the present. As it is, work is often wasted by choosing unimportant stations or stations which are too close together, and the values of the secular variation hitherto accepted are more often than not based upon a doubtful process of extrapolation. A proper investigation of secular variation is essential to a correct estimate of the distribution of terrestrial magnetic force both in time and space, and the author proposes that the International Committee take some steps to secure the co-operation suggested.

[Schmidt, *Terr. Magn.*, September, 1898.]

Earth's Magnetic Potential.—The methods which have been employed so far to represent the earth's magnetic potential in a series of spherical harmonics suffer from the serious defect that the different coefficients are not determined independently of each other. Thus, says Arthur Schuster, in the latest and most accurate computation of Adolf Schmidt, the value of the first and largest coefficient is found to be 1,872, 1,913 or 1,921, according as the expansion is supposed to end with terms of the third, fifth or seventh order respectively. If the value of the potential were known at all points of the earth's surface each coefficient might be separately determined by a direct integration over the surface of the sphere. But there are large tracts of the earth over which the magnetic forces have not been observed, and hence some form of interpolation is always necessary. On the other hand, a complete knowledge of the potential over any finite portion of the earth's surface is theoretically sufficient to fix it all over the globe, and the continuity of the potential and of its derivatives facilitates and justifies the process of interpolation. The author points out that the whole interest of the expansion in a series of spherical harmonics centres round the first few coefficients, and works out a simplified method based upon the above considerations.

[Schuster, *Terr. Magn.*, Sept., 1898.]

Strains due to Magnetisation.—C. G. Knott produced three series of nickel or iron tubes of increasing bore by boring out by successive stages an iron tube A, another iron tube B, half the length of A, and a nickel tube. Each tube was subjected to four distinct experiments, consisting in the measurement of the change of volume of the bore, the change of volume of the material of the tube, the apparent external change of volume of the plugged tube, and the change of length. From these measurements the principal coefficients of strain at the inner and outer walls could he completely determined. An element originally spherical became changed into an ellipsoid, whose principal axes were parallel to the axis of the tube and its radius respectively, and perpendicular to both. The corresponding coefficients of strain are distinguished as the longitudinal elongation λ, the radial elongation ν, and the tangential elongation μ. In nickel, λ is always negative, and μ and ν generally positive. In iron and steel, λ is positive in low and moderate fields, and negative in high fields. The cubical dilatation is always positive, whereas in cobalt it is always negative. The dilatation of the bore, $\lambda+2\ \mu$, is a differential effect. Hence its apparently capricious character.

[Knott, *Proc. R. S. Edinburgh*, Vol. XXII., No. 2.]

Earth Currents and Magnetic Disturbances.—S. Lemström describes the method employed by him for measuring the E.M.F. of the electric currents coming from the atmosphere, and quotes evidence showing that the variations of earth currents occur a short time (five minutes) before the magnetic perturbations, and that the former are more numerous than the latter. From the observations at Sodankyla it is, however, proved that not all magnetic perturbations are preceded by variations in the earth currents, but that these are most likely caused by earth-air electric currents. As a matter of fact, the magnetic perturbations in polar regions have a contrary direction to those in more southern countries, and at times of auroras the electric current from the atmosphere varies much, and must exert on magnetic instruments a

Digitized by Google

marked influence depending on their position relative to the space within which the electric current is moving. The magnitude of the variations of earth currents increases with the latitude in a very high ratio. There is a maximum belt of earth currents and of earth-air currents as well as of auroras. Two international circumpolar stations should be established, and existing observatories should make arrangements for earth-air current observations. It suffices to take a wire to the top of the nearest hill, since the conductivity of the wire does not interfere with the very large resistance encountered by these currents.

[LEMSTRÖM, *Terr. Magn.*, September, 1898.]

Photography of Coherer Sparks.—If further proof were necessary that the change of resistance in coherers is due to sparks between the particles, the evidence adduced by R. Malagoli would be valuable. He laid a sensitive plate with the film upwards, and covered it along two opposite edges with tinfoil. Between the two sheets of tinfoil he strewed some metallic powder, thus producing a two-dimensional coherer mounted on a sensitive plate. Wires were attached to the tinfoil, and dipped into mercury cups. On exposing the coherer to the action of electromagnetic waves, and developing, a tracing was obtained, looking like nothing so much as a colony of bacteria seen under the microscope. The bacteria were the paths of the minute sparks postulated by Lodge's theory. A somewhat similar appearance is produced by a discharge from a Leyden jar sent through the powder. When the layer of powder is so thick as to conceal the sensitive surface, no photographic impression is obtained, probably because the discharges occur in the interior of the layer, and are hidden from the plate by the bottom stratum. When no tinfoil sheets are used, no action takes place, and, on the other hand, the action is materially increased by suitably choosing the length of the terminal wires. There is evidently here some phenomenon of resonance.

[MALAGOLI, *Nuovo Cimento*, August, 1898.]

Dielectrics under Mechanical Tension.—The study of the properties acquired by a dielectric subjected to strain, whether by mechanical or electrical means, is of considerable difficulty owing to the complexity of the reactions. Ugo Panichi endeavours to unravel a portion of these changes by the study of the variation of the specific inductive capacity of stretched ebonite. The method adopted is novel and ingenious. An ebonite tube is suspended by means of a brass cap, which holds a glass tube projecting from it and serving as a kind of capacity indicator, communicating, as it does, with the mercury with which the interior of the tube is filled. Another brass cap is attached to the bottom, and weights are attached to it by means of a fine wire. The first problem is to find whether the internal capacity of the tube is affected by the stretching, as that would influence the calculations of the dielectric capacity. An increase of the internal volume is actually observed. The dielectric capacity is then determined by inserting the ebonite tube in a glass tube filled with mercury, thus obtaining a long cylindrical condenser with mercury armatures. The final result of all the experiments showed an increase of the dielectric constant of ebonite with tension, and proportional to the tension within the limits of the experiments.

[PANICHI, *Nuovo Cimento*, August.]

Earth Currents.—Writing on "The Interpretation of Earth-Current Observations," A. Schuster says: If two metallic plates are inserted into the ground, an electric current is found to traverse the conductor, and this is generally called the "earth current." It is not, however, obvious at first sight what the connection is between this observed current and that which traverses the ground when the earth plates are removed. The statement sometimes made that the observation gives the difference of potential of the earth at the two points at which the plates are inserted would be true, provided the connecting wire has a sufficiently large resistance, if earth currents were only due to chemical or thermo-electric forces. But as there can be little doubt that earth currents are chiefly, if not entirely, effects of induction, a separate investigation is necessary as to the interpretation to be attached to the galvanometer indications. A simple process of reasoning points to the importance of measuring the conductivity of the ground wherever earth-current observations are made. Samples of the soil taken from different depths would probably give different results, and would then indicate how the current density varies with depth.

[SCHUSTER, *Terr. Magn.*, September, 1898.]

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

(*Continued from page 808, Vol. XLI.*)

VI.—GAS GENERATORS.

Modern carbonising furnaces in which carbons are baked are all worked with gas, which is generated in a sort of furnace called the gas generator. The advantages in employing gas are the following:—

1. The easy regulation of the relation of the fuel and the air necessary for its combustion.
2. The facility with which the air can be mixed with the gas, by which the chemical action that results through combustion is accelerated.
3. The possibility of first heating the air that is used and thereby obtaining a higher temperature, while at the same time effecting an economy in fuel.

It would be practically or commercially impossible to heat the modern carbonising furnaces without using gas.

Principle of the Gas Generator.—Before describing the furnace it will be necessary to investigate the principles of the gas generator, which is one of the most important factors. In order to be able to render the matter clear, the writer has, to some extent, taken advantage of the admirable works of Prof. A. Ledebur and H. Stegmann.

The gas generated for such heating purposes is not manufactured in the same manner as the gas used for illuminating purposes, for in such processes the fuel is distilled, that is, the volatile parts are driven off, while coke remains behind. In a gas generator, however, nothing remains behind but ashes. Nor can a gas generator be called a furnace in the common sense of the word, for in an ordinary furnace the product of combustion is carbonic acid gas, CO_2, while the object of the generator is to produce carbonic oxide gas, that is, CO.

In Fig. 32 we have the principle on which all gas generators are constructed, and it will be seen that in reality it resembles an ordinary furnace or stove, in which there is a high layer of fuel. In the figure, *g* represents the grate on which the fuel is piled up to nearly the orifice *c*, into which the gas issues. At *b* there is an opening, into which fuel is thrown when necessary. In a gas generator it is of vital importance to keep the fire at a high temperature, by means of which the chemical and physical actions that result in connection with the fuel and air are accelerated. Not a partial but a complete combustion is the principle by which gas generators work in converting fuel into gas.

In an ordinary furnace the heat generated is generally given off to surrounding bodies, or used in one way or the other, whereas in the gas generator the heat, with the product of the combustion (*i.e.*, carbonic acid gas), acts as follows: The heat is imparted to the fuel over it, which gets heated to a high temperature, which dissociates it, causing any gases or hydrocarbons which the fuel may possess to be liberated and pass upwards. The carbonic acid gas which was formed, in passing this heated mass of carbon or carbon vapour, takes up another atom of carbon, and is converted into carbonic oxide gas. The fact that a great heat is necessary when reducing carbonic acid gas into the oxide gas is shown from the following theoretical considerations: The combustion of 1 kilo of carbon, C, produces about 8,080 thermal units (1 thermal unit being the heat necessary to raise 1 kilo of water from 0°C. to 1°)

* From a forthcoming book to be published by *The Electrician* Printing and Publishing Company (Limited). All rights reserved.

Digitized by Google

when transformed into carbonic acid gas, or when reduced into carbonic oxide gas gives about 2,473 thermal units. Now, in the reduction of carbonic acid gas into the oxide one atom of carbon is taken up by the carbonic acid, and we have $C + CO_2 = 2CO$. As this one atom of carbon is fixed it cannot be liberated before it has received sufficient heat, which heat is supplied from the combustion that produced the carbonic acid. Now, when we have the conversion of one part by weight of the carbonic acid gas into two parts of the oxide we have $2 \times 2,473 = 4,946$ thermal units, which, when subtracted from the 8,080 that the carbonic acid gas produced, leaves us 3,134, which represents the work done in converting the carbonic acid gas into the carbonic oxide gas. This heat, which is necessary for the conversion, must thus be present in the generator.

This conversion is, however, only one part of the actions going on in a generator, as the fuel, when it is coal, wood or turf contains other hydro-carbons with water perhaps, all of which are distilled by the action of the heat, which shows us again where some of the heat is also expended and absorbed. The nitrogen that comes into the generator with the air passes upwards, and mixes with the other gases, so that the gas used in heating the oven, or rather for carbonising, really consists of a mixture of several gases, some of which, like the carbonic acid gas and the nitrogen, may be called dead gases, as they do not support the combustion.

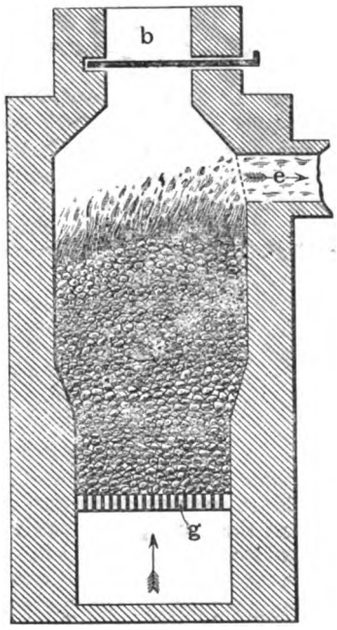

FIG. 32.—Principle of the Gas Generator.

If only coke is used as fuel in a gas generator we do not obtain such a mixture of gases as mentioned above, as the hydro-carbons have already been driven out of the coke, which is, in fact, pure carbon, containing also a little ash. In this case, if we suppose that no carbonic acid gas escapes, and that all is converted into the carbonic oxide gas, we obtain in weight or volume 34·3 parts of the carbonic oxide gas and 65·7 parts of nitrogen. 1 kilo of such a mixture when burned —that is, when its carbonic oxide is consumed by being converted into carbonic acid gas—gives about 824 Cal. or thermal units, while a cubic meter will weigh about 1·25 kilos. Of course, in reality these figures are lower, as there is always some carbonic acid gas that escapes and more air taken than is necessary. It must be remembered that air contains about 21 parts of oxygen and 79 of nitrogen, from which we see that an over-abundance of air, of which the oxygen is not all consumed, brings lots of nitrogen with it that dilutes and weakens our gas, so that it produces less thermal units per volume when burning. One of the main things in working a generator is to see that the fire is even throughout its whole cross-section, for if there is a spot where the fire is weak or where there is none at all the air will ascend without doing any work, and passes into the passage that leads to our oven. Not only does such air weaken the thermal qualities of the gas, it is also dangerous, as an explosion may follow by the formation of oxy-hydrogen.

It is well known and has been proved by experiment and practice that the conversion of the carbonic acid gas into carbonic oxide gas is accelerated by maintaining a high temperature in the generator, while at the same time the hot fuel should have a large surface with which the gas can come into contact.

The amount of fuel converted into gas in a given time, on which also the temperature depends, is proportional to the amount of air supplied, which depends on the draught and the resistance offered to the gases in their passage through the layers of fuel. The air is generally supplied to the generator by means of a blower, and in such a case can be regulated so as to force any amount of air that is necessary te overcome the resistance offered to the gases in their passage. Another advantage in using a blower is that the pressure of the gas is higher than it would be if only a chimney draught was used, and the chemical actions are performed better.

Another good way is to build the generator so that there are small channels around its sides through which the air first passes before it enters in at the grate. By this means the air gets warmed up, which means economy. The temperature with which the gases issue from the generator depends, of course, upon the nature of the fuel used and upon the care taken in handling. Fuel that has already been carbonised, as coke, charcoal, &c., produce hotter gases than those fuels which are composed of hydrocarbons that must be decomposed first by the generator, thereby absorbing large quantities of heat which could be otherwise taken up by the gases, while a good draught from the blower which generates large quantities of gases helps to attain a high temperature. Bunte found that by using coke, and having a draught of about −7mm. to −8mm. on a water manometer, the temperature of the gases issuing from the generator was about 1,000°C. Gas generators are generally built in different forms, as the form depends upon the nature of the fuel it is intended to use. In fuel we have a great variety: as coals of the anthracite and soft kinds, coke, charcoal, lignite, peat, turf, wood, sawdust, &c.

It may be mentioned that coke or charcoal give about the least trouble when running a generator, as they do not form much ash and do not cake or slag as many of the coals. When broken into small pieces we obtain an even mass that presents a large surface, and we get a gas that issues at a high temperature, while there is no danger of distilled matter condensing in the passages that lead to the oven. No doubt charcoal is too expensive; but there are many countries where coke is as cheap as coal, or cheaper, and in such places it would be advisable to use it. One of the main things in a fuel is the quantity of carbon it contains, and preference is to be given to that fuel whose unit weight of carbon costs the least. Most of the other fuels contain also hydrogen, oxygen, nitrogen, moisture and ash.

The following table shows approximately the volume and weight of gas that can be obtained from 1 kilogramme of fuel, supposing it to be free from ashes and moisture, and including also the carbonic acid gas and nitrogen:—

Coke or charcoal will	produce	about	6·5cbm.	= 8	kg. of gas.
Wood	,,	,,	,,	2·2	,,	= 2·8	,,
Turf and lignite	,,	,,	,,	2·8	,,	= 3·4	,,
Brown coal	,,	,,	,,	3·4	,,	= 4·0	,,
Mineral coal	,,	,,	,,	4·5	,,	= 5·4	,,

From the above table we see at a glance the advantage in using coke in the generator when it can be procured relatively as cheaply as other kinds of fuel. Coke, charcoal, wood, turf and coarse brown coal generally retain their form when in the generator, only shrinking more and more together, until they are at last reduced to powder, which falls either through the grate or gets mixed with the ash. Many other kinds of fuel, however, when heated, begin to split or crack, falling into small pieces, as lignite and some coals of the anthracitic class, and also some of the coals that are rich in gas and do not cake. When such kinds of fuel form high layers it may happen that this splinting and breaking of the material may clog up the passages that are necessary for the gases in ascending, hindering the conversion of the gases, and thus

Digitized by Google

diminishing the quantity. Such fuel is used in generators with special grates.

Coals that get soft when heated, or cake together into lumps, also often render it difficult for the gas to ascend, as they clog up the passages, thus rendering it necessary to use a blower to overcome such obstacles; in fact, as has already been mentioned, the form of the generator depends upon the fuel used.

Prof. Ledebur, in pointing out the influence of moisture or water in the fuel on to the temperature obtainable, when the gases produced from various kinds of fuel are burned, arrives at the following figures, supposing that the temperature of the gases and air as they reach the oven are at 0°C.:—

From	fresh-cut wood	the	gases	can produce about...	1,412°C.
„	air-dried wood	„	„	„ ...	1,600°C.
„	well-dried wood	„	„	„ ...	1,704°C.
„	peat or lignite	„	„	„ ...	1,642°C.
„	dried peat	„	„	„ ...	1,774°C.
„	old brown coal	„	„	„ ...	1,737°C.
„	mineral coal	„	„	„ ...	1,896°C.

From this table we see that it is economy to use fuel containing as little moisture as possible. In the above calculated temperatures it was supposed that the gases and air entered the oven at 0°C., whereas in practice they generally enter the oven at a high temperature, so that the real temperatures are higher than the table gives. The fuel used in a generator should always be stored under a shed, and, if possible, dried before using, especially such porous fuel as coke. For further information concerning fuel, &c., *see* Mr. E. T. Carter's "Motive Power and Gearing." (*The Electrician* Series.)

(*To be continued.*)

POLYPHASE TRANSMISSION OF POWER.

BY F. WALLIS.

The transmission of energy by polyphase currents has made much greater progress abroad than it has in this country, and, in addition to our national conservatism in adopting new methods, there are two main reasons for our backwardness. In the first place, there are but few sources of water power in Great Britain, and recently steam power can be obtained comparatively cheaply all over the country. In Switzerland and in America, where long-distance transmission has made such strides, water power in large quantities is constantly to be met with, and is naturally taken advantage of; while, again, in the mining districts of both America and South Africa, fuel can often only be obtained at very great cost, and consequently it is cheaper to transmit power over a great distance from one large centre, where water power or fuel can be more easily obtained, than to have a number of isolated plants.

Nevertheless, there is a considerable field even in this country for the transmission of power in large quantities over long distances—say 20 to 40, or even 50, miles; for not only might great generating stations be erected near the coal pits, where fuel can be obtained delivered to the boilers at 2s. 6d. per ton, but, further, the enormous power that runs to waste in our blast furnaces might be in part utilised for the generation of electricity. It has been estimated that, for every 100 tons of metal cast, energy sufficient to generate 2,000 H.P. for one week is wasted in blast-furnace gas, and that throughout the country about 2,000,000 H.P. is thus wasted

But quite apart from such problematic schemes there are many cases in which polyphase transmission might be advantageously employed. For instance, at Dublin where the generating station is only seven miles from the furthest substation and the pressure employed is only 3,000 volts, polyphase transmission has been found to give admirable results. Indeed, wherever it is desirable to work at a pressure of 2,000 or 3,000 volts or more, polyphase transmission offers many advantages. Again, in many cases where the generating station is within a few hundred yards of the area of supply, the polyphase system may be profitably adopted, owing to its suitability for motor work. This particularly applies to the case of the transmission of power in works where motors form the chief part of the load. And it must be borne in mind that even though there may not be many openings for long-distance transmission at voltages of 10,000 or so in England, many such transmissions are required in the colonies and elsewhere abroad, and it is preferable that the necessary plant should be installed by English engineers.

The question thus arises, What is the greatest distance to which electrical energy can be economically transmitted, and how do the various systems of transmission compare with one another? The largest circuit yet employed has been the experimental one between Frankfort and Lauffen, a distance of 100 miles, over which 300 H.P. have been transmitted at 8,000 volts, three-phase currents being employed; 4,000 H.P. have also been transmitted on the three-phase system at 10,000 volts over 24 miles at Sacramento, and 1,400 H.P. at 11,000 volts over 35 miles at Fresno, Cal., not to mention the Niagara-Buffalo line, and many others. There are also several two-phase lines at work. Of single-phase alternating lines, that at Rome may be mentioned, where 2,000 H.P. are transmitted at 6,000 volts from the Falls of Tivoli, 18 miles distant from the city. M. Thury and others have also installed several long-distance continuous current plants, of which that at Geneva, where 400 H.P. at 6,600 volts are transmitted over 20 miles, is the longest; though the Brescia line, over which 700 H.P. are transmitted 12 miles, is worked at the highest voltage, namely, 1,500. In the case of many of these transmissions, where water power is employed, it must be remembered that the power available is greatly in excess of that required, and that consequently very considerable losses in the line and plant could be permitted.

Abroad, transmission of power is almost invariably carried out by bare, overhead wires. In England no such transmission on any large scale has yet been tried, and it is more than probable that the Board of Trade would insist on insulated cables being laid either underground or by the side of a railway, or in some such thoroughly safe and efficient manner, whenever a high voltage was employed. And in many ways this would be an advantage, for any long-distance transmission would necessarily be on a very large scale and any breakdown, which might easily occur with overhead wires, would cause great loss to the community. Further, overhead wires have great inductive effects, and in a crowded country like England would cause much trouble. The underground mains would, of course, be either concentric or laid very close together.

In other countries the conditions are, as a rule, entirely different. The chief consideration is generally small first cost, and, consequently, bare overhead conductors are almost universally employed. But, even with these, there are limits to the voltage which may be employed; not, indeed, in the apparatus at the ends of the line, for transformers can be made to safely stand almost any voltage but in the line itself. In a very dry climate 20,000 or 30,000 volts may be safely employed, but in a damp and foggy atmosphere, even 10,000 volts may be too high for satisfactory working, owing to moisture collecting on the insulators, and so causing short-circuits.

But, granted a long-distance transmission, the question still remains, How does the polyphase system compare with the direct-current and with the single-phase alternating? Now, though direct currents have been employed by M. Thury over considerable distances at very high pressure (*e.g.*, the 15,000 volts at Brescia), there are many disadvantages connected with such a system. In the first place, as M. Thury himself states, the maximum output of a high-pressure continuous-current dynamo is about 45 amperes at 3,000, or, at most, 4,000 volts; hence, for generation at 15,000 volts, four or five machines must be coupled in series; and likewise, wherever it is desired to tap the mains, another four or five machines in series must be run as motors, each either helping to drive a common shaft, from which a large generator may be driven to supply the lower potential current required for distribution, or driving its own smaller generator direct. In other words, large units with the corresponding gain in efficiency and in first cost cannot be employed with the continuous-current system. And, further, since commutators must be employed at the full

Digitized by Google

potential of line, the risk of accident to the attendants or to the machines themselves is very great. On the other hand, the employment of the direct current admits of a saving in the weight of copper in the line as compared with any of the alternating systems, the relative figures for direct current, single-phase, two-phase, four-wire and three-phase circuits being 0·50 : 1·00 : 1·00 : 0·75, assuming the same maximum potential difference in each case. As a matter of fact the gain in copper is even greater, for in almost all alternating circuits the power factor is less than unity, and consequently a greater current has to be carried than corresponds to the power transmitted. On the other hand, in the above figures it is assumed that the maximum alternating E.M.F. is $\sqrt{2}$ times the effective E.M.F., and though this is approximately true it should be remembered that the disruptive discharge due to an alternating E.M.F. is sluggish; that is to say, does not at once follow the applied E.M.F., so that, to take an instance, an alternating E.M.F. of more than $\frac{15{,}000}{\sqrt{2}}$ effective volts is required to produce the same disruptive effect as a continuous-current E.M.F. of 15,000 volts. Further, there is no electrolytic effect with an alternating current, nor does the osmotic effect, whereby moisture creeps to the negative pole of a continuous-current circuit, exist. Of course, with underground cables these effects would not, under normal circumstances, be present; yet should by any chance a minute leak develop they would at once manifest themselves.

On the whole, in the majority of cases, it will be found that though there would be a considerable saving of copper in the line, the continuous-current system is placed out of court by the fact that the generators and motors have to be split up into comparatively speaking small units, and that a considerable element of danger is always present owing to the necessarily more or less exposed commutators being at high potentials above the earth.

The single-phase alternating system is well adapted for the transmission of power over long distances when it is simply a case of one receiving station where the one or two large motors convert all the energy at once into its mechanical equivalent. In the text-books it is shown that the system requires more copper in the line than the three-phase, the proportion being 100 to 75; but, as large single-phase motors, such as have just been referred to, are always synchronous and there is practically no lagging current in the line, whereas with a three-phase transmission the power factor will rarely exceed 80 per cent. and the line wires have to be increased proportionately in size, it follows that there will not in practice be much difference in the weights of copper employed. The real objections to the single-phase system are two in number—first, that the motors employed have to be of the synchronous type, and, secondly, that rotary converters designed to transform single-phase alternating currents into continuous current cannot be built for an output much above, say, 50 kilowatts, on account of the excessive sparking at the commutator, this sparking being due to the great fluctuations in the alternating current in the armature. A synchronous motor might, of course, be arranged to drive an entirely separate continuous-current dynamo and the sparking difficulty so got rid of, but the cost of the two machines would considerably exceed that of a polyphase rotary converter, and the efficiency of the conversion would be lower. But the chief objection to the single-phase system is undoubtedly that first mentioned, namely, that synchronous motors have to be employed which cannot be started without external aid, and further require separate field excitation. This does not matter so much in a large transmission, where power is simply sent from one end of a line to the other in large quantities, for in such a case the cost of the exciter, and of the battery of accumulators or the small non-synchronous motor required for starting purposes, does not bear a large proportion to the total cost of the installation, nor is the extra attendance required for these a serious item. But where only small motors are concerned such complications become prohibitive; and though many induction and other self-starting motors have been brought forward, none have yet proved themselves sufficiently satisfactory for general adoption, or at least, as a matter of fact, have not yet been generally adopted. It should be added that synchronous motors may be started not only by small subsidiary self-starting motors, or by driving their exciters as motors from a battery of accumulators, but also by supplying the exciters from the alternating current mains when, provided their field-magnets are laminated, they will run as alternate-current motors. But this method involves the use of the laminated fields and other complications, and does not seem to be often employed.

With the polyphase system the difficulty of self-starting is entirely done away with. Even synchronous polyphase motors will start themselves, owing to the reaction of the eddy currents induced in the solid pole-pieces—provided the pole-pieces are solid, and not laminated at the tips, as is often the case; but as the resulting torque is not very great, the motors have to be started light and the load only thrown on when they are running in synchronism. Synchronous motors have the great advantage of a power factor of nearly unity when properly excited, and hence, if three-phase synchronous motors are employed, there is a saving of 25 per cent. of the line copper over the single-phase system. But in spite of their lower power factor, induction motors are far more generally employed on polyphase circuits. With these there is no difficulty in starting, even under full load. Small motors up to 10 H.P. or so are generally made with squirrel-cage rotors, and these when starting under full load take for a short time a current of two or three times the normal full-load value. Larger machines are provided with a variable resistance in the rotor circuit, and will start under full load, taking only the normal current. For cranes and hoists the rotors are wound to have a considerable resistance, and a starting torque of even five times the normal can be obtained.

Further, the polyphase system has the advantage of being peculiarly well adapted for use with rotary converters. A three-phase current can thus be transformed into a single-phase, a two-phase, or a continuous current, though for conversion into single-phase or two-phase it is far simpler and more efficient to use static transformers. For conversion into continuous current, however, rotary transformers must be used, and since in polyphase systems the flow of power is constant there is no difficulty with sparking at the commutator. Indeed, the tendency to spark, and the demagnetising effect of the armature, is far less than with continuous current dynamos, since the armature reactions of the two circuits tend to neutralise one another. Thus we are told that the 600 kilowatt converters at Niagara will give 900 kilowatts without sparking.

It is rather a drawback to the use of the rotary converter that as a rule it requires a static transformer to reduce the polyphase voltage before it reaches the machine. The reason is that continuous currents are almost always required at low voltage and a rotary converter with only one armature winding has a fixed ratio between its polyphase and continuous current voltages, the former being lower than the latter. But even were any voltage ratio possible it would still be undesirable to introduce high potential currents into a revolving armature, and static transformers would have to be employed. From what has been said it must not be inferred that static transformers must necessarily be employed with motors, for such is not the case. The polyphase circuits can be, and in large sizes generally are, led into the stationary portion of the motor, where they can be as well and safely insulated as in a transformer itself. Small motors, however, cannot be wound for high pressure except at prohibitive cost—the limit for a 20 H.P. motor being about 1,000 volts—and with these static transformers must be employed.

Thus in a large transmission system large motors will take current direct from the high-pressure mains, while for smaller motors one or more distributing centres with large static transformers will be established. Lamps may also be run from the low-pressure polyphase circuits, being connected either between the three mains in a three-phase system, or, preferably, between each of the mains and a fourth balance wire running to the junction of the three circuits on the low-pressure side of the static transformer, in which case the

Digitized by Google

latter must be star wound. In a balanced three-phase system the sum of the three currents is always zero, and so a fourth return wire is unnecessary, but where the load may be unevenly distributed, as is the case when lights are run from the mains, a fourth wire will take the unbalanced current and the voltage regulation is more satisfactory than if no return wire were used. As against the extra weight of the return wire this system has the advantage that the voltage between the mains is raised to $\sqrt{3}$ times that required by the lamps, and consequently the mains themselves take less copper. On the other hand, in many cases in practice there is no difficulty in obtaining a good balance even without the complication of a fourth wire. The motors on the circuits act as automatic regulators, for should the voltage between any pair of mains fall owing to extra lamps being switched on to that circuit, the current in the corresponding branch of the motor windings will fall. The back E.M.F. in these branches will rise and the current still further fall, while at the same time the currents in the other two branches on the motors will rise to make good the deficit, and the voltages will once again become approximately equal. Nevertheless, many engineers prefer the two phase system with four wires, where, as the two circuits are electrically independent of each other, they can be independently regulated. The lamps are then each on their own circuit, and only in the motors are the two phases brought into play. For this reason it has been suggested that it would be better to employ three-phase transmission in the line on account of the saving of copper (the weight for the same maximum potential difference as compared with the two-phase 4-wire system being in the proportion of 75 to 100) and at the receiving points to transform by static transformers to the two-phase system.

A third method is to transform from three-phase to continuous currents by the use of rotary converters, and much can be said in its favour. In the first place rotary converters can be made to act not only as transformers, but also as boosters, for the field winding may be compound, and sufficient series turns employed to actually make the full load voltage greater than at no load, the phase relations in the polyphase circuit being altered thereby. Again the periodicity of the polyphase circuits may be too low for the satisfactory working of lamps (neither arc nor incandescent lamps should be worked under 40 revolutions per second), and then the only thing to do is to distribute by continuous currents. Further, the regulation of a continuous current voltage is easy; and, of course, continuous current motors work satisfactorily. Such a combined system is particularly well adapted for traction purposes where on account of induction troubles and of three-phase currents requiring at least two trolley wires, it is as a rule impossible to use anything but continuous currents for the working of the cars. On the other hand, the use of the polyphase system throughout is in many cases more satisfactory. Where motors alone are to be driven the conversion to continuous current is quite unnecessary; for, as has been said, large motors can be supplied directly from the high pressure mains, and smaller ones only require static transformers in place of the more costly and less efficient rotary converters. Where, however, the distribution is mixed, that is to say, where motors and lights have to be run from the same circuits, the question is not so easy of solution even when the frequency is high enough for lighting purposes. Although in some cases, as has been mentioned, the regulation of voltage on polyphase circuits has been found to be a comparatively simple matter the experience obtained has perhaps not yet been sufficient for us to say that this will always be the case, and it may be taken as a maxim that wherever regulation will be a difficult matter requiring great care and attention it will be more economical in the end to install some simpler system, even at an increased first cost. Again, though accumulators may be charged by means of rectifiers or rotary transformers from alternating circuits their use is almost entirely confined to continuous current distribution.

So far as the motors are concerned the polyphase system more than holds its own. Not only will induction motors start under full load, but their regulation is an easy matter. Synchronous motors will run at absolutely constant speed, no matter what the load, and well-designed induction motors of from 2 H.P. to 100 H.P. drop only from 8 per cent. to 4 per cent. in speed at full load. They thus act like continuous-current shunt motors. Their efficiencies between these sizes vary from about 76 per cent. to 92 per cent., and could be designed to be greater still. As a rule, the regulation of speed is effected by a variable ohmic resistance in the rotor circuit, though in cases where large starting torque is not required, auto-transformers, which inductively reduce the voltage of supply, are often employed. Alteration in speed may also be effected by alteration of the number of stator poles, by changing the connections from star to mesh, and by coupling two motors together, so that the rotor current of the first machine supplies the stator of the second. As a rule, however, regulation is effected by altering the resistance of the rotor circuit, though this method has the disadvantage that when carried out to any large extent the efficiency is considerably reduced. The polyphase motor has, further, the great advantage over the continuous-current motor of requiring no commutator. It is also of very strong mechanical construction, and requires little or no attention. Likewise for equal power, its weight is less than that of the direct-current machine; while, at the same time, it can stand very considerable overloading for a short time. There is very little difference in efficiency, power factor, starting torque, and exciting current, between the three-phase and the two-phase motor, what slight difference there is being in favour of the three-phase.

A great deal has been said concerning the low power factor of polyphase systems. For transmissions in which the load consists chiefly of induction motors, the factor varies from about 0·65 to 0·85. As a rule it will be about 0·75 or 0·8. The motors and transformers, and not the line, are the chief sources of the lag of current behind the E.M.F., though the result of a low power factor is increased size of plant all round. The coil can, however, be compensated for to a considerable extent by the employment of a few large synchronous motors, which not only have no lag when properly excited, but when over-excited will still run as motors, with the current leading the E.M.F. They then, in fact, act as condensers. One American firm actually sends out condensers with its motors; but, generally speaking, the condenser cannot yet be regarded as a commercial article. In the matter of power factor the advantage of the three-phase over the two-phase motor is so small as to be practically negligible. It must be remembered that as the load decreases the power factor also decreases, so that when the motor is running light, and absorbing but little energy, the current it takes is still 20 to 30 per cent. of the full-load current.

With the introduction of polyphase motors frequencies have fallen considerably from those of 100 $\sim$ per second, and more employed some years ago, for electric lighting. The higher the frequency the cheaper are the transformers; but, on the other hand, if a motor is to run on a high-frequency circuit at a given speed, it must have an increased number of poles, and this, in small sizes at least, means increased size and cost. Further, the higher the frequency the greater the magnetic leakage and the magnetising current required. Also, the higher the frequency the greater is the skin effect in conductors, and consequently the more finely must they be subdivided. At Niagara a periodicity of 25 has been adopted, and this is but little lower than that of the majority of polyphase transmissions in America. In Europe a rather higher figure, of somewhere over 40, is more general, in order that the circuits may be employed for lighting as well as for motive purposes.

Lighting Concessions in Turkey.—It has been announced twice that an imperial iradé had been issued, granting to Sir Ellis Ashmead-Bartlett a concession and monopoly for the electric lighting of Smyrna and Salonica. The *Daily Mail's* Berlin correspondent is informed, however, that a similar iradé for the town of Smyrna had been granted to a German firm in 1889. Possibly the present of an Arab steed may prove the more useful of the two gifts from the Sultan.

SOME LARGE INDUCTION MOTORS.

The accompanying Fig. 1 shows one of two motors built by Messrs. Brown-Boveri and Co. for the second locomotive of the Jungfrau electric railway. A full description of the line and equipment appeared in our issues of Sept 23 and 30. We may remind our readers that each locomotive carries two three-phase star-wound induction motors, designed to run in parallel at 760 revolutions per minute, and to develop each 125 to 150 B.H.P. when supplied with current at 500 volts and 38 revolutions per second frequency. The weight of each motor is 2·6 tons, and the locomotive complete weighs 13 tons. To this weight must be added that of two passenger carriages, containing each 40 passengers, which the locomotive must be capable of propelling up a 25 per cent. gradient. The rheostat, shown in course of construction in Fig. 3, is placed in series with the rotor of the motor, to avoid starting it on short-circuit.

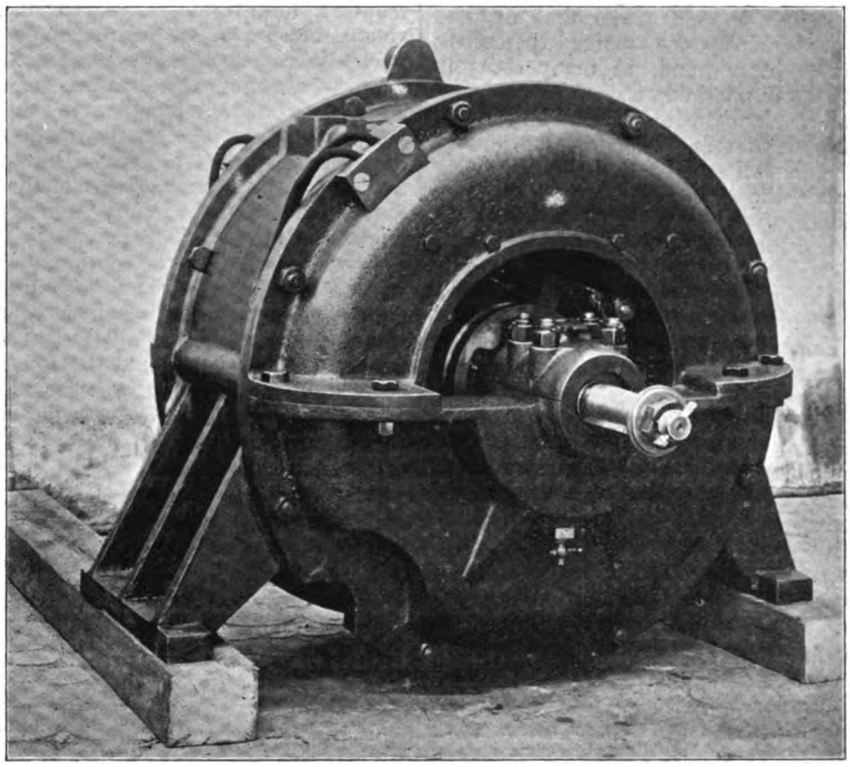

FIG. 1.—Motor for Jungfrau Locomotive.

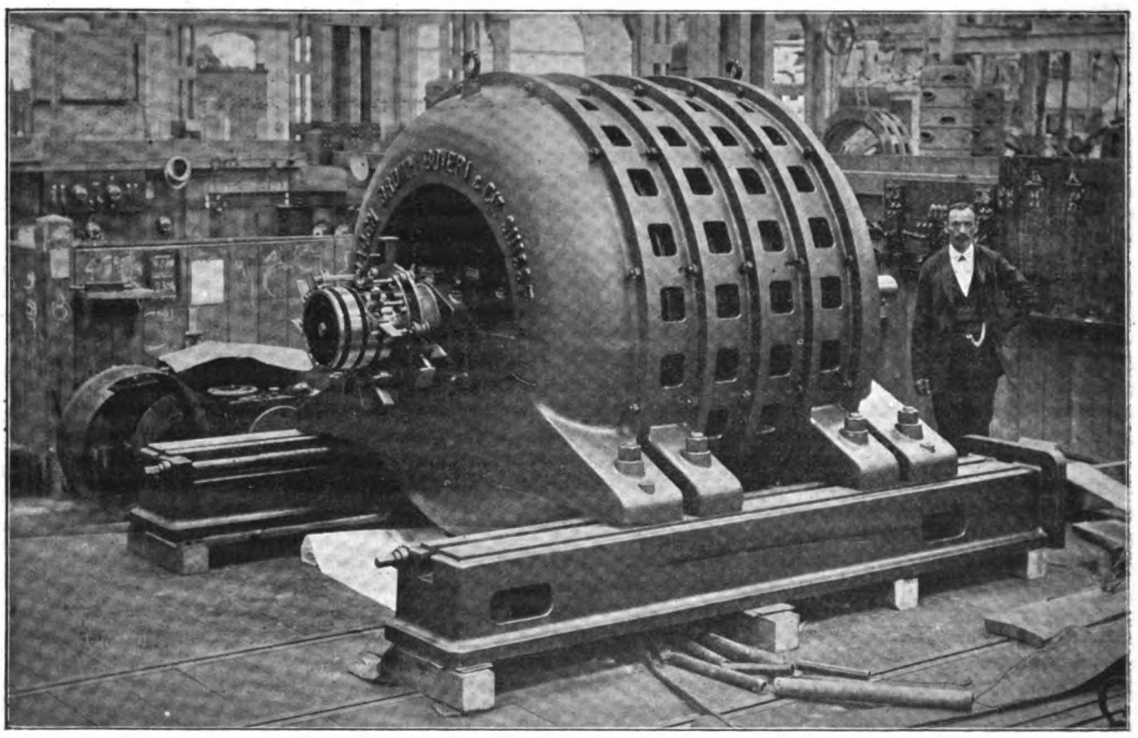

FIG. 2.—One Thousand Horse-Power Induction Motor.

No resistance is placed in the stator circuit, the coils of the stator being connected directly to line through a switch and fuses. Fig. 2 is from a photograph of a two-phase motor where it will be coupled directly to a Sulzer centrifugal pump working against a head of 466ft. The motor is designed for an output of 1,000 B.H.P. at 544 revolutions. It is wound for

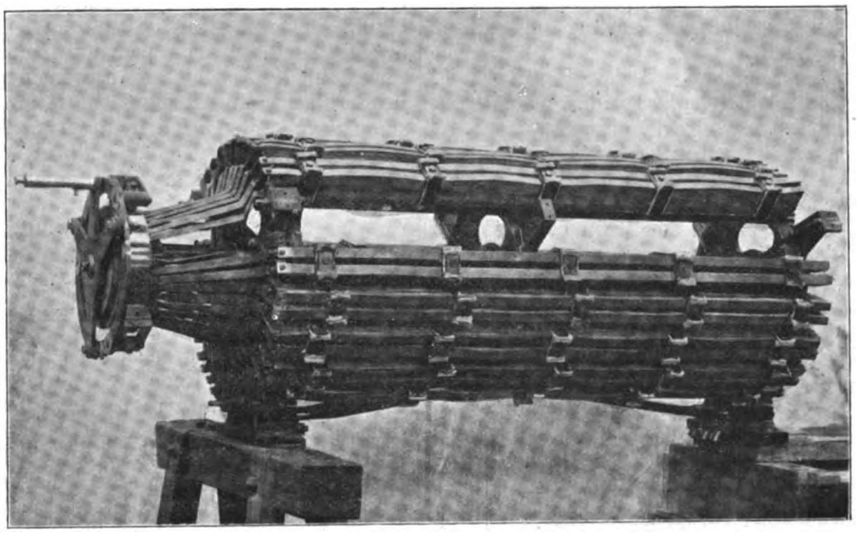

FIG. 3.—Regulating resistance.

built by the same firm, who claim that it is the largest induction motor in the world. It has been built for the city of Geneva, a pressure of 2,500 volts and a frequency of 46 ∿ per second. The weight of this motor complete is 27 tons.

THE HIGGINS TYPE-PRINTING TELEGRAPH APPARATUS.

The latest pattern of type-printing apparatus designed by Mr. F. Higgins, of the Exchange Telegraph Co., has many points of novelty. Although not constructed on any entirely new principle, the numerous improvements in detail make it a decided advance upon its predecessors, and render a detailed description of interest.

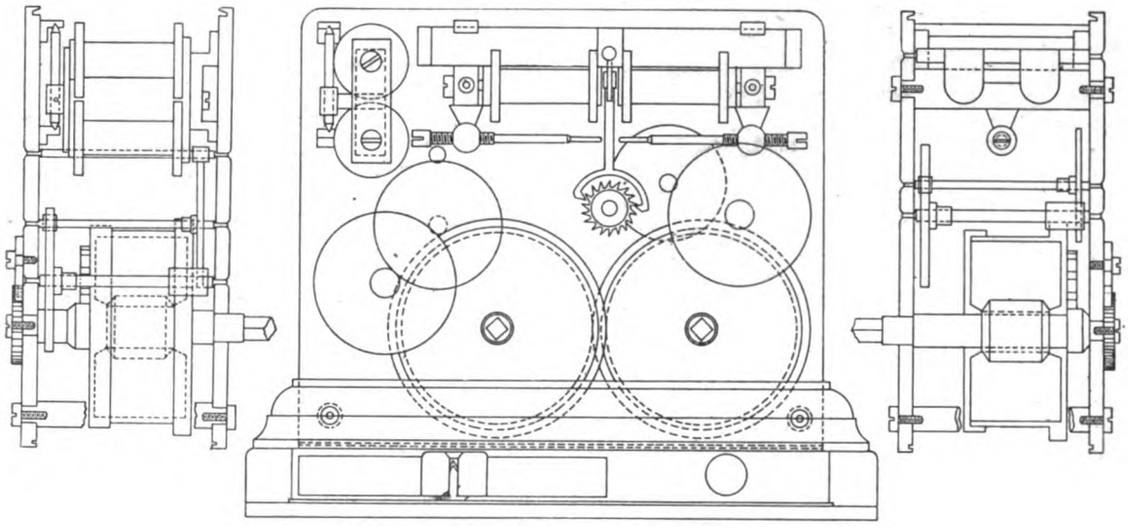

FIG. 1.—Receiver of the Higgins Type-Printing Telegraph Apparatus.

The transmitter is of the Wheatstone A.B.C. type having a horizontal circular keyboard with 36 keys, one for each letter of the alphabet, one for each numeral from 2 to 9, one for the negative sign, and a zero or blank key. The working current is generated by a magneto machine driven from a treadle by the operator, and the same movement drives through gearing a vertical spindle carrying a toothed wheel which normally engages with and carries a pawl round the circle formed by the keys, th gearing being so designed that the motion of the pawl from one key to the next corresponds exactly to a half revolution of the magneto armature and therefore to the duration of current in one direction. As there are 36 stops, there are 36 reversals of current to each complete revolution of the pawl round the key circle.

So long as all the keys are up, the toothed wheel on the spindle engages with the pawl (which is shaped like a bell crank), and the pawl in rotating holds by friction a lever against a contact button, and by so doing completes the line circuit through the magneto machine. On depressing any one key a small lever attached to it is pushed forward. As the spindle rotates one arm of the pawl strikes this lever and disengages the other arm from the toothed wheel, causing the pawl to stop at that point. At the same time it allows the contact to fall away from the contact button, disconnecting the current generator from the line. When a key has been depressed it remains down until the depression of another, the keys being restored by an arrangement of a thin chain and pulleys attached to them. Thus, supposing one key down, on

Digitized by Google

depressing any other on the board the first one rises, allowing the pawl to engage with the revolving toothed wheel and to be again carried forward. The line circuit is then completed until the pawl strikes the lever of the newly-depressed key, when it again stops and the current to line is interrupted as before. A pointer is fixed to the pawl shewing the operator when and at what key it stops.

The receiver, shown in elevation and end-elevation in Fig. 1, consists of two trains of wheels driven by springs. One train works the type wheel, and is controlled by an escapement, A, attached to an armature, which is pivoted between two pairs of electromagnets, and so arranged as to oscillate in synchronism with the alternations of the line current. Each movement of the escapement allows the train of wheels to rotate the type wheel $\frac{1}{36}$th of its circumference. Thus 36 reversals of current cause the type wheel to make one complete revolution. As already stated, the pawl in the transmitter also makes one complete revolution with 36 reversals of

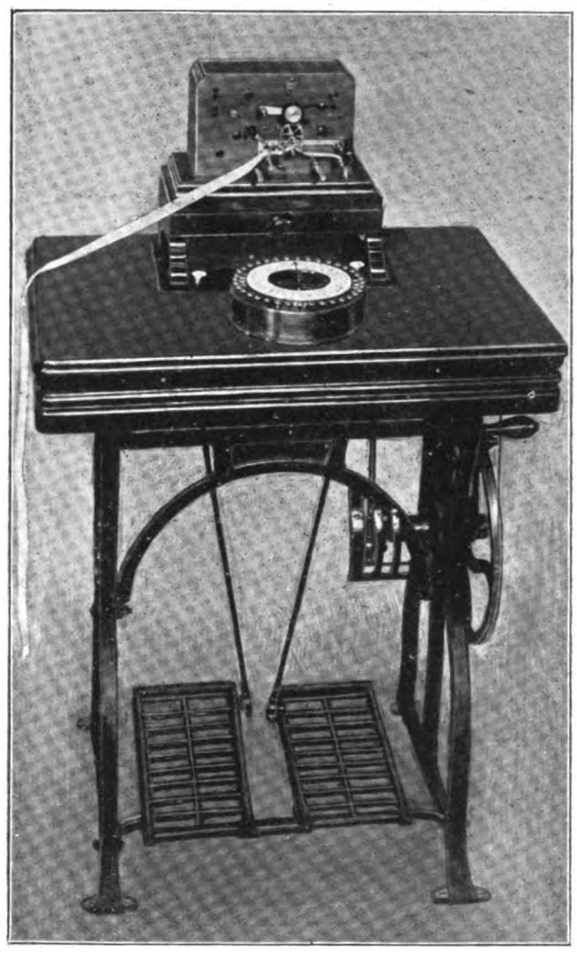

Fig. 2.—General View of the Higgins Type-Printing Telegraph Apparatus.

current, so that the pawl, pointer and type wheel move in synchronism, and, if arranged so that when the pointer is opposite any letter or figure on the keyboard of the transmitter, the same sign on the type wheel is undermost, then at whichever letter or figure the pointer is afterwards stopped the type wheel will be in a corresponding position, and the two will remain in synchronism as long as there is no external cause to upset the motions.

A synchronising mechanism is placed in the apparatus in case it should get out of step. In the receiver is a small lever, engaging by means of a pin a screw thread cut in the type-wheel spindle. This pin carries the lever against a stop, fixed to and rotating with the type-wheel spindle. After a certain number of revolutions of the type wheel spindle (if the printing mechanism is not in the meantime brought into play) this step holds it in position when the blank figure is undermost. Hence, if all the keys on the transmitter keyboard be lifted and the current allowed to flow to line for a few revolutions of the pointer, the type wheels in the receiver are turned a certain number of revolutions and then stop, with blank key ready for printing. If the blank key in the transmitter is now depressed, its pointer now stops at the blank. The pressing down of the key, as will be shown directly, actuates the printing mechanism, and the latter raises the lever, which is preventing the type-wheel spindle from rotating and releases the latter, the lever being at the same time pulled back by a spring to the commencement of the screw thread. The type wheel is now free to move, and rotates in synchronism with the pointer.

The second train of wheels in the receiving apparatus works the printing mechanism. It is controlled by the armature of an electromagnet so adjusted that when the alternating current is flowing the armature is held up and does not vibrate with the reversals of the current. When the current is interrupted this armature falls and releases an escapement which allows a sprocket wheel to rotate through a distance equal to the pitch of the sprockets. Each sprocket travels past a lever carrying the paper roller, and in passing lifts the lever at one end, causing the latter to press the paper against the type wheel. After lifting the lever end a certain height the sprocket slips past, and the lever drops back to its original position. At the same time it actuates the feed mechanism for the paper, which is moved forward by the proper distance in readiness to receive the impression of the next letter.

A detail, which, though a small one, makes a material difference to the possible speed of working, is that the type wheel is connected to its train of clockwork through the medium of a spring. Thus, both at starting and stopping, the spring helps to counterbalance the inertia of the mechanism.

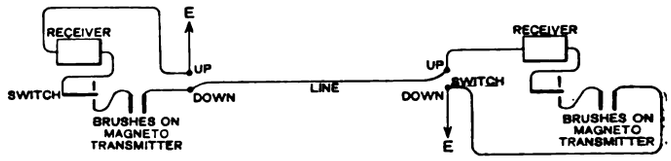

Fig. 3.—Connection Diagram.

The following is a summary of what occurs during the transmission of a signal: The operator presses down the key of the transmitter which corresponds to the letter or figure he wishes to signal; this stops the pawl, interrupts the line circuit, and leaves the type wheel of the receiver motionless, with the letter signalled undermost. At the same time the interruption of the line circuit causes the printing armature to fall back, releases the train of wheels which move the sprocket wheel, and forces the paper-carrying lever sharply up against the type wheel, prints the letter, and as the sprocket wheel continues to move forward the paper-carrying lever falls back, actuating the feed mechanism, and the paper is fed forward a certain distance. On depressing the key for signalling the next letter the first key rises, the pawl re-engages with the revolving toothed wheel, the current again flows and causes the type wheel to rotate, attracts the printing armature which it holds up until the current is again interrupted by the transmitter pawl striking the other lever of the second depressed key, and the same cycle of movements as before takes place. Fig. 3 will help to explain the action of the apparatus.

The main springs working the train of wheels are sufficient for the printing of about 1,000 words, and an indicator has been provided to show when re-winding is necessary.

One great advantage in this apparatus is that the working currents are generated by a very powerful magneto machine, which not only ensures the correct motion of the escapement but might in some cases enable the apparatus to be worked over a line so faulty as to cause a breakdown with other descriptions of instruments.

The apparatus is well constructed, compact, and any necessary adjustment is made with facility. Repairs will be seldom required but their execution should be easy. An experienced operator can work up to a speed of 25 to 30 words a minute with the instrument, and the manipulation is so easy that an unskilled person could learn it in a very short time.

Instruments have been working between the Exchange Telegraph Co.'s office in Cornhill and their office in the Haymarket, with an added resistance of 1,500 ohms in circuit. Successful experiments have, we understand, been made between London and Folkestone, a distance of 60 miles. Trials were also made, with satisfactory results, at the Post Office before the Duke of Norfolk, Sir Spencer Walpole and Mr. Preece; and at the War Office before Lord Wolseley and members of his staff.

ELECTRICAL TRANSMISSION OF POWER IN MINING.

At the ordinary meeting of the Institution of Civil Engineers on Nov. 15th, Mr. W. B. Esson read a Paper with the above title.

The disadvantages attendant upon expensive transport of ore had been to a large extent neutralised by the electrical transmission of power. By using electrically-transmitted power the crushing mills could be placed at the mine, and the serious expense of transporting the ore to the site of the water-power could thus be saved. Generally, electricity furnished the only practicable means for transmitting power for mining operations, and the ease with which a copper wire could be carried over any kind of country, together with the plastic nature of the material, rendered the electrical conductor the simplest and most reliable of all vehicles for power transmission. Before deciding whether power transmission should be adopted, it was generally necessary to compare the cost of the alternative methods of (*a*) Bringing fuel to a mine to work the machinery by steam, and (*b*) Transmitting power electrically to a mine from a generating station situated at some convenient position for utilising existing water-power. The working expenses, added to the interest on the capital invested, made up in both cases the annual cost; but the question as to which alternative should be adopted depended largely upon the hours of working. For working 12 hours a day a result in favour of steam might be shown, while for a 24 hours' day the evidence might be largely in favour of water, depending upon the capital required to be expended in the hydraulic works.

The plant erected at the Sheba Gold Mining Company's mine for the electrical transmission of power to the crushing mills, five miles distant, was described, and the cost of milling was shown to be 1s. 8d. per ton of ore as against 6s. 1d. per ton when aerial ropeway transport was used, and £1. 12s. 6d. per ton during the time of ox-waggon transport. The water-power was obtained by a dam across the Queen's River, two miles above the generating station, to which the water was conveyed partly in open race and partly in tunnel. The maximum head derived was 32ft. The turbines were of the Victor horizontal type, driving a countershaft at 300 revolutions per minute by ropes, and were together capable of developing 396 H.P. They were provided with Snow governors, acting directly upon the turbine gate.

The generating-plant consisted of three alternating-current dynamos supplying current at 3,300 volts. Each generated two alternating currents having a phase difference of 90deg., and was capable of giving an output of 150 electrical H.P. The armature was stationary, and the field magnets rotated at a speed of 400 revolutions per minute. The stationary high-pressure coils were mounted on laminated iron sectors, which were laid close together in a strong cast-iron cylindrical shell made in halves to form the armature. This was 54in. in internal diameter by 12in. wide, and within it the field-magnet rotated. Each coil was wound on a former, and had 63 turns of double cotton-covered wire 0·12in. by 0·09in. in seven layers. The adjacent layers are carefully insulated by micanite cloth, while the complete coil was boiled in paraffin, and was afterwards heavily covered with impregnated tape to a thickness of $\frac{1}{16}$in. In addition, during the process of mounting, a trough of fibre was interposed between the coil and the iron core. There were 14 coils on the armature, the seven upper coils being for one phase and the seven lower coils for the other; each, therefore, contributed about 470 volts to the circuit. The coils were displaced to give the phase-difference by the interposition of idle laminated sectors.

The field-magnet was excited by a single coil and consisted of a steel wheel, from the rim of which projected two series of poles, N on one side of the coil and S on the other. The poles were expanded on the face, and were curved to form a circle of 16 alternate faces, which were presented to the armature core, with an air-gap of 0·33in. The exciting coil was wound on a cast-iron drum placed in the middle, between the projecting poles, and was positively driven by a couple of pins screwed into the steel casting. It terminated in a pair of gun-metal rings lying side by side upon, and insulated from, a substantial cast-iron bush, which in turn was keyed upon the shaft. The exciters were ordinary two-pole upright machines. For throwing the alternators into parallel the incoming alternator was plugged on to the synchronising bars, and when approximate synchronism was indicated by the hot-wire voltmeters it was thrown into the main circuit by closing, through a large choking-coil, a path between the synchronising bars and the main omnibus bars. The choking-coil prevented a large rush of current, due to difference of phase, between the alternators, though at the same time allowing sufficient current to pass to pull the new machine into step.

The current was transmitted by cables to the mine, and at the receiving-house the pressure was reduced to 100 volts for driving motors and lighting the workings. The frequency at which the plant worked was 53·3 per second. The conductors were laid underground, and consisted of concentric cables insulated with impregnated jute covered with lead and armoured. There was no fall of potential due to self-induction in the cables, nor had the current in one pair of conductors any inductive effect on the neighbouring pair. But when overhead wires were employed, the conductors, being of necessity some distance apart, there was not only a fall of potential due to self induction in the lines, but, unless precautions were taken, the mutual induction of the circuits carrying currents of a quarter-phase displacement tended to produce inductive dissymmetry throughout the system. Every length of cable was tested to a pressure of 10,000 volts before leaving the maker's works. Lightning-guards were fitted at each end of the line, to prevent accidents to the machinery from the effects of the induced charge.

At the receiving-house there were four transformers of 50 kilowatts capacity, two for each phase; these reduced the pressure from 3,000 volts to 100 volts. The use of oil for the transformers had been discarded after the experimental trials. The motors were of the induction type; their construction was fully described, and the author also explained their working under varying conditions, and gave a brief account of the laws which governed their action. The crushing mill at Sheba worked night and day; and in one year, of the possible 365 days of 24 hours each, the pressure had been cut off the conductors for only 4 days 8h. 22min., which had been chiefly occupied in inspecting the water-race, overhauling the belts, ropes, &c., and in executing general repairs to the machinery. The efficiency of the plant from the turbine shafts at the generating station to the motor shafts at the mine might be taken as 70 per cent.

SOME AMERICAN SUGGESTIONS TO EUROPEAN ELECTRIC TRAMWAY BUILDERS.*

If America may presume to make Europe certain suggestions regarding the building of electric tramways, a patient hearing may be hoped for, as it is generally recognised in all countries, we believe, that American experience in this particular branch of engineering is quite complete, though by no means wholly admirable. America has wasted—if we can call it wasting—so many millions in experiments that it observes, with something like a shudder, the danger that the same old weary course of trial and failure may be gone over again abroad.

First, as to roadbed. This is the foundation not only of a railway plant, but of its financial success as well. Nearly always by far the largest single item in the investment account, it is likewise almost the largest in the operating account if proper charges for repairs and depreciation are annually made. While by no means sure that the best present American practice is final or will be justified by results, we are confident that European practice in track building is in important respects less conservative and is inadequate for electric traction. European engineers do not appreciate, we believe, the tremendous pounding which the electric railway tracks have to stand from the motor cars, to say nothing of waggon traffic. It is true that there is no reciprocating motion in the motor, as in steam locomotives, to promote this pounding; but the slightest imperfection in the joint creates differences of level between the rails, which cause the car to fall upon the following rail and hit it a blow which greatly increases the trouble. With single-track roads both rails at an imperfect joint are hammered, and a hollow is thereby formed. Electric cars are always popular, are nearly always crowded with people, or are run at short intervals, and the blows thus being multiplied either in weight or in frequency, and their quickness of application being increased by high speed, the result, as we have found it in America, is that the best construction which we can make for joints and rails is hardly strong enough. It may be urged that the concrete foundations for track usual in Europe will cure this trouble; but this has not been American experience where tried, though there is undoubtedly some advantage in concrete foundations. The true remedy, as near as we can now judge, is, first, to use 60ft. rails, and so reduce the number of joints; second, to butt the joints together in paved streets; third, to increase the carbon in the rail, thereby giving it a hardness which will prevent the battering of the head; and, finally, to use a "square shouldered" section, so as to permit of accurate fitting of the joint plates and a strong vertical support—this whether the support be of iron cast around the joint or of wrought iron girder fish plates. Brittleness

* From the *Street Railway Journal*, of New York.

Digitized by Google

in the rail due to hardness is not so much to be feared in tramway practice as softness, for a broken rail does not mean an accident, as on steam railroads, but merely the replacing of the rail. Hardness is advantageous not only at the joints but along the entire rail, since rails which have been in service longest show a wearing away of the rail head far greater than in horse railway practice, due, of course, to the self-propelling motive power employed.

Track special work—frogs, crossings, switches, &c.—ought, also, to be made of the best material, and with the greatest care. Some of the capitalists who are building electric tramways in foreign countries complain that they cannot get good special work from European makers, the latter still using cast iron largely, and following the old horse tramway methods, with results disastrous both to wheels and the special work itself. Transition curves should, of course, be made in all cases, and the greatest pains taken to provide for the easy movement of the car at all points on the road, curves as well as tangents. Great Britain is undoubtedly ahead of America in the care taken with track return circuits, and, in fact, has gone to an extreme in demanding low voltage drop in the earth. While a 7-volt drop generally means less electrolytic effect with pipes and wires, it does not always do so, since it is *current* which produces these troubles, and current can be obtained from low voltage in quite as great quantity as from high, providing only that the earth resistance be sufficiently low. In overhead construction, Europe has paid more attention, perhaps, to the ornamental than has America, and this is certainly right. With attractive poles and a simple and unobtrusive wire structure there can be no reasonable complaint on the part of municipalities with the overhead electric system, certainly in view of the great advantages of electric traction.

Power station equipment should be in the fewest possible units consistent with reliability of service. In early American practice we had stations with 20 and 30 small units. To-day these have nearly all been replaced, at heavy expense, by fewer and larger ones. Perhaps an ideal station for most conditions is one made up of five units, of which four are of the same size, and one but half that size. The small unit takes care of the night service, two of the larger should handle the every day traffic at its maximum, a third may be added on holidays and special occasions, and a fourth is always in reserve. A station arrangement of this character requires foresight in determining the probable maximum requirements of the future, as to load, but when this is once estimated it is better to determine the ultimate sizes of the units and purchase two (one for reserve), even in the beginning of the re-equipment than to buy smaller units to be replaced afterward by larger ones. It is needless to say that direct-connected units should always be employed, as belts are out of date for street railway work.

No fixed rules can be laid down for rolling stock except that all cars should be made as strong and durable as possible—far more so than for horse railway traffic. The tastes and habits of the people and local conditions otherwise must govern the seating arrangements and forms of cars chosen. Roof seats are popular almost everywhere, and though little used in America, it is not because people would not like them, but because, in the long run, it is believed that they would prefer speed of car and comparative immunity from accident. Americans have not been educated to climbing up and down a stairway to the car roof. It is impossible, of course, to speak within these limits in any but the most superficial and fragmentary way upon this general subject of adaptation of American experience to European conditions.

ELECTRICITY WORKS ACCOUNTS.

Bolton Municipal Electric Supply Works.

The Bolton undertaking commenced electricity supply on October 81, 1894; our analysis this week, therefore, covers the accounts of the third completed year of working.

The borrowed capital amounts to £60,000, out of which £57,038 has been expended, representing £76 per kilowatt of plant capacity. Exceedingly satisfactory is the rapid progress shown not only as regards increase in business, but also in the matter of economy of working; thus during 1897-98 the number of customers had risen from 237 to 390, and the equivalent 8-c.p. lamp connection from 19,477 to 32,000—an increase of 64·3 per cent. The output shows an increase on the 1896-97 figure of 55 per cent., being this year 341,888 units sold, while the average price obtained has dropped more than a penny to 4·7d. per unit.

A great reduction in the total costs per unit is noticeable which brings them down to 2·05d.—a figure well below the average of stations of similar output. Works costs contribute to this reduction by the amount of 0·5d., and management and property charges to the extent of 0·26d.

The net result of the working is a reduction in the ratio of costs to revenue of from 49 per cent. to 44 per cent. and a working profit of £3,771, which has been disposed of by an allocation of £918 to the depreciation fund, £1,410 to the sinking fund and the payment of £1,443 as interest on loans.

The detailed record below of the progress of the undertaking is interesting, and it may be stated that the lamp connection has been considerably increased since March last, being now the equivalent of 40,000 8-c.p. lamps with 500 consumers. We are also informed by the Corporation's electrical engineer that the capacity of the station has been increased from 750 kilowatts to 1,000 kilowatts, and that there are over 3,000 lamps awaiting connection to the mains and applied for.

Derby Municipal Electric Supply Works.

Electric supply at Derby was started a year before it was at Bolton, viz., on October 10, 1893; therefore, its fourth financial year was completed on March 31, 1898. Up to this date £60,784 had been borrowed at 3 per cent., and £65,909, representing £105 per kilowatt of plant, expended on capital account.

The output for 1897-8 was 340,783 units sold, being an increase of 15½ per cent. over the output of 1896-7. The average total revenue per unit comes out at 5·54d., as compared with 5·6d. for the year before.

Very substantial economies in working have been effected, as the total actual expenditure out of revenue has fallen in spite of the increased output, so that the costs show a reduction of nearly a penny per unit. It is chiefly through the items of works costs that the economy has been effected.

The working profit for the year was £3,221, representing 5·17 per cent. on the mean capital. £1,847 was set aside to the sinking fund, and £1,749 paid as interest on loans, resulting in a deficit of £374 to be met by the rates.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1876).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 6d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician' Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

THE ROTATORY CONVERTER.

The session of the Institution of Electrical Engineers has opened auspiciously with a Paper by Dr. S. P. Thompson, which has the double merit of being topical and intrinsically valuable. Within the last year, the adoption on some of the more important electric railway works of alternating currents to transmit energy, to be eventually utilised in the form of continuous currents, has drawn the close attention of engineers to the processes and means of effecting this transformation. That such a means should be adopted at all seems on the one hand a triumph for the advocates of alternating currents, but from another point of view it might be taken as a declaration of the final bankruptcy of the alternating current motor for railway work. The validity of either of these views may be presently reconsidered. Contrary to what we might expect from Dr. Thompson, the historical information given is somewhat limited, and substantially the Paper confines itself to the consideration of one type of converter, viz., that having a single field with an armature having one winding, connected at one side to a commutator, and at points depending on the number of phases of the alternating current to slip rings receiving the alternating current. The Paper then deals with the questions arising out of such an arrangement, viz., the ratio between the continuous current and alternating current E.M.F.'s, the total load in the form of continuous current the machine will carry for any specified range of heating, whilst the effects of armature reaction, both on the brush-sparking question and on the regulation and parallel running are dealt with, but not in a conclusive manner. Dr. Thompson's Paper places the matter in a logically reasoned form, which helped by graphical means and novel diagrams, presents the general description admirably, whilst for the accurate working out of special cases tables arrived at by various

Digitized by Google

investigators are given. In this and our two preceding issues, we have given our readers a *résumé* of one of these investigations, published by Mr. G. KAPP in the *Electrotechnische Zeitschrift*, opportunely accompanying the present Paper and discussion. The features, perhaps new to most engineers, disclosed by these Papers are, first, the superiority for use with such converters of four-phase currents derived from a two-phase supply over three-phase currents; second, the fact of the very unequal heating of the wires on different parts of the armature winding. As to the first of these points, the investigations, above referred to by Kapp, Steinmetz and others, show that the possible output increases with the number of phases, and even at six phases the limit is by no means reached, it then being double of that possible with single-phase currents; and it may be that this points to a line of evolution where the generator will have as many coils as a continuous-current machine, the line wires will be the connections between the armature coils and commutator, and the commutator rotated synchronously at the receiving end will deliver continuous current. In the discussion which ensued upon Dr. THOMPSON'S Paper, we find that divergence of views between men equally capable of forming an opinion to be expected in a subject in which so little comparatively has been done. Notwithstanding the use of these converters for electro-chemical purposes at Niagara, and for railway work in America and England, there seemed a strong tendency of opinion that the gain in efficiency and first cost over the motor generator was (except when exact regulation is not wanted) rather dearly bought, owing to the inherent difficulty of regulation, whilst Mr. E. K. SCOTT, impliedly supported by Dr. THOMPSON, suggested that in the case of the Central London Railway there was no reason whatever to effect the conversion at all, as polyphase motors might equally well have been used. To summarise the views of the various speakers, it seems generally admitted that the single-phase rotatory converter is not, except in small sizes, an advantageous machine to use, and the experience of Prof. MENGARINI at Rome may be taken as a typical instance. There the single-phase converters are being replaced by motor generators, on account of difficulties with sparking due to the periodic fluctuation of the armature field, and to the difficulty of hunting when running in parallel. It is, further, generally conceded that, where the continuous-current pressure has to be regulated over more than a few volts, the boosters, variable-ratio transformers, or equivalent devices absorb any advantage over the motor-generator. Then, again, except where the frequency is low, say 40 $\sim$ per second or lower, the large number of poles and brushes on the machines places them at a disadvantage. But where three, four, or more phases are used, with low frequency currents, and where no very extended range of regulation is necessary, the rotatory converter has given and will continue to give satisfaction.

No doubt the reading of the Paper and the discussion will be fruitful in directing further attention to the subject, both on its theoretical and experimental side. One suggestion may be incidentally offered here. Whereas in a continuous-current generator the only change in current is that occurring under the brush when the coil is not in circuit, in the case of a rotatory converter it occurs during every part of the revolution. This effect of self-induction should, it seems to us, receive attention, both as to the modification it produces in the ratio of E.M.F., and also in its effect as to pulsations in the continuous current delivered.

THE THEORY OF THE ROTARY TRANSFORMER.

BY GISBERT KAPP.

(COMMUNICATED BY LLEWELYN B. ATKINSON, A.M.I.C.E.)

(*Concluded from page 153.*)

Four-phase Rotary Transformer.—A two-phase system of currents can only be utilised in a rotary transformer by a system of connection to the armature analagous to that called the *mesh* coupling in the case of three-phase currents, with the result that the working is that of a four-phase system. In Fig. 5, a_1 a_2 are the points of connection of phase a, and b_1 b_2 those of phase b. The brushes are d and f. If we consider the direction of the continuous current as positive, in the quadrant $a_1 b_1$, both alternate currents are negative; in the quadrant $a_1 b_2$ the current of the a phase is negative, that of the b phase positive.

The resultant two-phase current in the quadrant $a_1 b_1$ is

$$i = -J(\cos\alpha + \sin\alpha),$$

where J is half the maximum value of the current in each phase.

This expression holds good for all positions, the angle α being reckoned from the line $o d$.

Bearing in mind the trigonometrical relation,

$$\cos\alpha + \sin\alpha = \sin\left(\alpha + \frac{\pi}{4}\right)\sqrt{2},$$

we have

$$i = -J\sqrt{2}\sin\left(\alpha + \frac{\pi}{4}\right),$$

and the maximum value of the resultant alternate currents is

$$J\sqrt{2},$$

the current and E.M.F. being considered in phase as before. The maximum value is reached for $\alpha = \frac{\pi}{4}$, that is, in the case

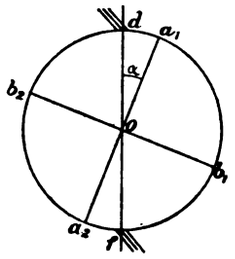

FIG. 5.

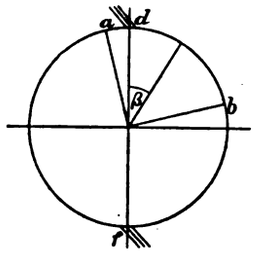

FIG. 6.

where the quadrant is exactly in front of the pole. In this case also is the E.M.F. of the $\frac{z}{4}$ wires contained in the quadrant a maximum, whilst it is zero when the quadrant is symmetrically disposed about a brush.

The effective value of the alternate E.M.F. is

$$e_a = \sim \mathrm{KN}\,\frac{z}{4}.$$

The coatinuous current E.M.F. is

$$e = \sim \mathrm{N}z,$$

so that

$$e_a = e\frac{k}{4}.$$

If the effective value of the current in a quadrant is J, the power of each phase of the alternate current in a quadrant is $Je\frac{k}{4}$, and for the whole armature JeK.

This is also (neglecting the losses) the power in the continuous current, so

$$2ec = JeK,$$

$$J = \frac{2}{K}c.$$

The maximum value of the resultant alternate currents in a quadrant is $\sqrt{2}$ this value, or

$$J_1 = \frac{2\sqrt{2}}{K}c,$$

$$J_1 = \eta c.$$

Digitized by Google

The value of K depending on the proportion between the coil width and pole pitch, we have for $m=\frac{2}{3}$, $\eta=1{\cdot}32$, and for $m=\frac{1}{2}$, $\eta=1{\cdot}21$.

If there is a difference of phase, J_1 must be increased in the proportion $\cos\phi:1$, and the value of η must be divided by $\cos\phi$.

Next, the power lost in copper heat may be considered the assumption of no-phase displacement being made. To simplify the calculation, the angle β (*see* Fig. 6), which the centre line of the quadrant makes with $o\,d$, may be used, and

$$\beta=a+\frac{\pi}{4},$$

$$i=c\eta\sin\beta.$$

In order to arrive at the lost power in each quadrant, integrate the work between limits $\beta=o$, $\beta=\pi$, and divide by the semi-periodic time. The integration is taken at three stages, viz., $\beta=o$ to $\beta=\frac{\pi}{4}$, $\beta=\frac{\pi}{4}$ to $=\beta\frac{3\pi}{4}$, and, lastly, $\beta=\frac{3\pi}{4}$ to $\beta=\pi$. The last is numerically equal to the first. In the instantaneous position (shown in Fig. 6), the current in

$$ad=c+c\eta\sin\beta,$$

$$bd=c-c\eta\sin\beta.$$

Taking into consideration the length of the coil the differential of the lost power is

$$\left\{c^2(1+\eta\sin\beta)^2w\left(\frac{\pi}{4}-\beta\right)+c^2(1-\eta\sin\beta)^2w\left(\frac{\pi}{4}+\beta\right)\right\}dt,$$

and

$$dt=\frac{d\beta}{2\pi\sim}.$$

The first and last stages of the before-mentioned integral are given by the expression

$$A_1+A_3=\frac{c^2w}{2\sim}\int_0^{\frac{\pi}{4}}\left(1+\eta^2\sin^2\beta-\frac{8}{\pi}\eta\beta\sin\beta\right)d\beta,$$

which evaluated gives

$$A_1+A_3=\frac{c^2w}{4\sim}\left\{\frac{\pi}{2}+\eta^2\left(\frac{\pi}{4}-\frac{1}{2}\right)-\frac{8\sqrt{2}}{\pi}\eta\left(1-\frac{\pi}{4}\right)\right\}.$$

For the second stage the lost power is

$$A_2=\frac{c^2w}{4\sim}\int_0^{\frac{B\pi}{4}}\left(1+\eta^2\sin^2\beta-2\eta\sin\beta\right)d\beta.$$

Evaluated this gives

$$A_2=\frac{c^2w}{4\sim}\left(\frac{\pi}{2}+\eta^2\left(\frac{\pi}{4}+\frac{1}{2}\right)-2\eta\sqrt{2}\right).$$

The total power lost in one quadrant is

$$\frac{A_1+A_2+A_3}{\frac{1}{2}}=(A_1+A_2+A_3)2\sim,$$

and for the whole armature is four times this value, or,

$$P_v=8\sim(A_1+A_2+A_3).$$

Working this out with the above values gives the following result:—

$$m=\tfrac{2}{3},\quad K=2{\cdot}13,\quad \eta=1{\cdot}32,\quad P_v=2{\cdot}24c_2w,$$
$$m=\tfrac{1}{2},\quad K=2{\cdot}32,\quad \eta=1{\cdot}215,\quad P_v=2{\cdot}20c_2w.$$

If the same armature is driven by mechanical power developing continuous current $2c_1$, the loss would be

$$P_v=6{\cdot}28\,c_1^2w,$$

and substituting the values above, we find that for

$$m=\tfrac{2}{3},\quad c=1{\cdot}67c_1,$$
$$m=\tfrac{1}{2},\quad c=1{\cdot}69c_1.$$

In other words, as a rotary transformer, the machine will deliver from 67 per cent. to 69 per cent. more current than when mechanically driven. The figures also show that for a four-phase machine the ratio m is unimportant.

Three-phase Rotary Transformer.—Following a similar process, Mr. Kapp investigates the case of a three-phase transformer, with these results:

$$m=\tfrac{2}{3},\quad K=1{\cdot}94,\quad \eta=1{\cdot}45,\quad P_v=3{\cdot}28c^2w,\quad c=1{\cdot}38c_1,$$
$$m=\tfrac{1}{2},\quad K=2{\cdot}12,\quad \eta=1{\cdot}33,\quad P_v=3{\cdot}02c^2w,\quad c=1{\cdot}44c_1;$$

that is, the machine delivers from 38 per cent. to 44 per cent. more as a rotary transformer than as a mechanically-driven generator.

Six Phase Rotary Transformer.—By carrying the independent ends of the secondary coils of the three phases of a three-phase system, to slip-rings connected to opposite points of the armature, the system becomes a six-phase one, and a similar investigation may be carried through in this case.

Finally, all these results may usefully be summarised in a table, in which for comparison the values obtained in the limiting case proposed by Steinmetz, where the field is sinusoidal in value, are also set out.

Table showing the Output of Rotary Transformers as percentage of the Output of the same Machine used as a Mechanical Generator:—

Type of transformer and phase displacement.		Theoretical limiting case by Steinmetz.	Pole width.	
			$\frac{2}{3}$	$\frac{1}{2}$
Single-phase	$\cos\phi=1{\cdot}0$	85	88	95
	$\cos\phi=0{\cdot}9$	...	81	88

ROTATORY CONVERTERS.

The following is an abstract of the discussion which took place at the Institution of Electrical Engineers on November 10th and 24th, in connection with Prof. Silvanus P. Thompson's Paper on this subject. Speakers who have returned their proofs revised are denoted by an asterisk:—

DISCUSSION.

* Mr. M. B. FIELD said that the manner in which the author had dealt with the distribution of the currents flowing in the armature and the local heating of the different parts of the armature was very interesting, and particularly so because he had dealt with these matters without formulæ and without complicated diagrams, and, therefore, people like himself could readily understand his arguments. But he felt that particulars were missing of the way in which these rotatory converters worked in practice. Dr. Thompson had asked him to give some more particulars of the 30 kilowatt converter he referred to in his Paper. Fig. 14 showed the winding scheme, but there was a slight difference between that and the actual machine, viz., the slip rings were shown connected to the opposite side of the armature to what they actually were. In designing this machine he thought he gained a great advantage by choosing a number of conductors divisible by 16. The slip-ring connections divided the winding up into eight parts, and not only should all these subdivisions be exactly similar, but each should contain an even number of conductors; so that all the slip-ring connections might be brought out at the same end of the armature. The advantage of having such a number as this was again of value, because they got a number of commutator segments which was divisible by four, so that the brushes stood upon the commutator segments in exactly similar positions. When one brush was short-circuiting they were all short-circuiting, and this way they had perfectly symmetrical windings. The table immediately following Fig. 14 was taken when the converter was running as a continuous motor. The field was separately excited and the commutator voltage adjusted until the speed was exactly 1,200 revolutions per minute. He had the good fortune to be in the power station where this converter was supplying the excitation for the generators when there was a short-circuit on the mains. The converter was connected in parallel with a small turbine driven exciter, which was only about one-seventh the capacity of the converter. Of course, the voltage sank down to zero at once and the machinist wanted to switch everything out. But they let everything alone. The short-circuit lasted for about 15sec., a fuse blew, and the tension came up and nothing happened. Although the tension was reduced to zero, the converter was still in step and was delivering its proper share of the current. The heating of the poles of this converter was very considerable, but he attributed that principally to the proportion between the width of the slot and the air gap. He thought the question of pole heating a rather important point. One might imagine that the pole heating was very considerable in these converters, owing to the very peaky form of the resultant current in the armature conductors. Prof. Thompson had dealt very fully with the comparison of the heating of armature conductors in the rotatory converter and the corresponding continuous current machine, but he had not dealt with the pole heating. He noticed that

Digitized by Google

the Central London Railway converter had laminated poles, but the Oerlikon converter had solid poles, and it would be very interesting if Dr. Thompson would tell them how many of the machines he had shown upon the screen at the previous meeting had solid poles, and how many had laminated poles. Dr. Thompson had exhibited one converter with two completely independent windings for working on a three-wire system. It was interesting to note that two converters working in parallel on the three-phase side could not be connected up to a three-wire distribution on the continuous current side. It was, however, possible to make use of the neutral point of the transformers on the three-phase side as a starting point for the neutral wire of the three-wire continuous current distribution. He had gone into this matter about six months ago, and found that if they got one side more loaded than the other they got a small current superimposed on the continuous side of three times the frequency. With regard to a variable ratio, this was of considerable importance when they wished to vary the voltage in a simple way. The auxiliary booster on the same shaft was expensive on account of the large size of the commutator needed. Something quite special had to be made. It was easy to see that if they insisted upon a variable conversion ratio they must get reaction in the machine. They could only obtain one at the expense of the other. There was one other way of making the continuous-current voltage depend upon the excitation, and that was by the use of transformers with much magnetic leakage. With such transformers, if the current lagged the voltage fell, if the current led the voltage rose. In a rotatory converter they had simply to either over or under-excite in order that the current might lag or lead. He had heard of a case where the transformer was specially leaky in order to obtain a large variable ratio. With regard to the hunting of converters, Dr. Thompson had thrown out the suggestion that the cure for the hunting effect or oscillating effect might be found in designing their rotatory converters with very stiff magnetic fields, which are not very easily disturbed by the reaction effect of the armature current. This might help them a great deal. Alternate current designers were all tending to work in the direction of small air-gaps and producing very stiff fields, but it did not necessarily follow that because a certain air-gap was necessary to keep down the self-induction of the armature winding the whole of it must be at the pole surfaces. Mr. Kapp in 1894 worked machines with small air-gaps. Between each segment of the armature he interposed an air-gap of ⅛in., and claimed that this was of special advantage in keeping down the self-induction. The main thing was to bring the windings as near as possible to the poles, so that the effects of the armature currents could not blow the field out sideways.

* Mr. JAMES SWINBURNE said that if they would start by thinking of the ordinary direct-current motor generator, they had a machine in which the power was poured in at one pair of wires and poured out with absolute uniformity at another pair, so that the only work the machine had to do was really to work its own commutators; but as soon as they came to working with alternate currents the machine had to do a little more. It had to be able to store up the energy by going slower or faster during a fraction of a period only. It must, of course, preserve its synchronism. If they could get over that difficulty or reduce the amount of energy to be stored up in each portion of the apparatus, they would get a machine very much smaller, for in the extreme case of two direct-current machines the armature was simply rotating to work the commutator. But there was another thing that came in at once, and that was that as soon as they had a current in the opposite direction on the armature they could do away with their air-space. In early days the air-space was very little understood. Now the chief application of the air-space was to get the excitation on the fields approximately right or properly proportionate to the excitation on the armature, to avoid cross induction and armature reaction generally. There was another matter which came in at the same time, and that was the lead of the brushes and sparking. Dr. Thompson had put this down as being first known in 1888, but it was known very early in the eighties. He did not think the question of "hunting" of parallel machines was confined to this particular converter. The hunting of machines was first discovered by Mr. Harrison, who made some experiments at Faraday House some years ago. His own explanation was that, suppose they had two alternators in parallel, let them imagine that one was doing a little more work than it ought to, and the field got altered by the armature reaction. Some years ago Lord Rayleigh pointed out in a lecture on electrical tuning forks that the fork would work only because the self-induction was so great that the pull both ways was not in synchronism with the contact in the mercury, and he also had explained the fact that the lag was the cause of the working. There was a simple application of the same idea to parallel machines. If the machine corrected itself instantly there would be no tendency to get out of step, but if a machine was doing too much work, then it altered its field, and even went on doing too much work when the field was right again, with the result that it got on the other side and did too little work. Then correction and over correction in the opposite direction took place. Mr. Field seemed to think they could get over this hunting effect by having non-laminated magnets. A "stiff bristly field," to quote Mr. Field, was a kind of nomenclature he objected to—simply because he did not know what it meant. He noticed that Prof. Thompson had altered the nomenclature from "rotary" to "rotatory." He would remind the Professor that the Institution was an electrical institution, and not a high school for girls. He (Mr. Swinburne) approved of the word dynamotor. As an English word it was indefensible, and that was why he had introduced it. There was not much to add to what Mr. Field had said as to the question of altering the E.M.F., but he did not think it was quite correct to take an armature uniformly all round and then find where the uneven losses and heat occurred. Some years ago he wanted to design one of these particular machines for transforming single alternating current into direct current, and, instead of working uniformly all round, he attempted to use wire of different sizes all round. But the calculations involved in this were so troublesome that he gave up the idea. Still, he thought such a thing would have to be worked out eventually with large machines, but the difficulty with it was that these machines were special machines for small air spaces, and if they had the wires embedded they then got into the difficulty of the holes not being uniform if they had the windings of different sizes.

* Mr. W. B. ESSON said that, if he remembered rightly, the rotary converter was first exhibited at the Frankfort Exhibition. Dr. Thompson had referred to the work of Lahmeyer. He did not remember very clearly about Lahmeyer, but he remembered very clearly the number of interesting machines exhibited there by Schuckert and Co. These machines fascinated most of the visitors from England. When he came home the first thing he did was to put slip rings on a dynamo and watch the results obtained in taking alternating or continuous-currents from the machine. The Table he exhibited showed the ratio between the alternate current and

direct current very clearly. The machine was bipolar, and was tested, having a direct and alternate current taken out of it at the same time. The alternate current was kept constant at 30 amperes while the direct was increased, and the table also showed the effect of the reaction in the field due to the alternating current. At no load the machine gave 95 volts; immediately the alternating current was put on, it gave only 85 volts. When tested as a compound machine, the volts very soon rose. Working with the ordinary two-phase arrangement, *i.e.*, taking two alternating currents out of the machine in addition to the direct current, the volts only reached 70. He thought these were the first experiments made in this country on a direct-current dynamo with slip rings. As a general principle, he supposed that the more tappings they had in the continuous current winding for the alternating current, the more energy they could convert with the apparatus. For instance, with a single-phase machine there were two tappings; with a three-phase, three tappings; and with a two-phase, four tappings. The result was that they got out of the two-phase the greatest amount of energy for a given size of machine, and, at any rate, with rotatory converters, two-phase distribution was very much superior to three-phase, because something like 25 per cent. more energy was got out of the machine. With regard to the see-sawing action which had been mentioned, it certainly did require more investigation, but he would like to ask the author whether it was not true that it was extremely necessary to have the form of wave given by the generator correspond exactly with the wave given by the alternate current part of the convertor. A good deal of the see-sawing action also, he thought, was due to the fact that the ratio altered with the excitation of the field magnets. It was rarely that the ratio was exactly the same in different convertors, and the consequence was that currents passed between the machines. This he had been told by American engineers of great experience. There was a great deal of difficulty in deciding whether they should use a rotatory converter or an induction motor with a dynamo attached to it. And these difficulties increased when it was known that in some stations where rotatory converters had been in use they were now installing alternate-current motors with dynamos attached instead, and in other cases *vice versâ*. He thought the rotatory converter had mostly been used in tramway work, in which the absolute regulation of the voltage was not of paramount importance. Again, a tramway generally worked across a two-wire system, whereas in lighting a three-wire system was necessary, and when they came to balance up the cost of, say, an induction motor with an ordinary dynamo coupled to each end against that of a rotatory converter constructed for a three-wire system, with all the complication of poles and brushes entailed, the balance would be little, if any, in favour of the latter. At the present moment he was connected with the laying down of the first two-phase central station in this country, and they would have to convert in several districts alternating into direct

Digitized by Google

current. This was being done by induction motors with dynamos coupled at each end of the shaft, and working on the three-wire system. One of the reasons for not using rotatory converters he confessed was because they did not know so much about them as they did of the other type, and what information they had got was not wholly satisfactory. Another point was that rotatory converters were not suited for such frequencies as could be employed for lighting. When they got a converter suitable for a frequency of 50, it had just as many poles as the ordinary alternator with all the brushes added.

Mr. H. M. HOBART sent a communication in which he stated that to his mind the cure for all erratic tendencies of the kind mentioned in the Paper was to be found in using for the generating plant steam engines which had a more uniform angular velocity. This was also the very foremost of the difficulties which attended the paralleling of alternators. He considered that there was now no necessity for tolerating this phenomenon of "hunting." He had some cases in mind where considerable difficulty was at first encountered on this score. The rotaries were specially designed with laminated pole pieces for the purposes of eliminating eddy currents, and with perfect speed conditions this would have resulted in a higher commercial efficiency than with solid pole faces, since with the latter there was a higher eddy current loss than for the corresponding continuous current generator owing to the cyclic rise and fall of the alternating current component of the resultant current in the armature face conductors as they swept past the solid pole faces. But the elimination of this loss deprived the machine of the use of the induced currents in the pole face for tending to keep the armature rigidly in synchronism. It became necessary to resort to devices to correct the trouble, and these devices involved some sacrifice as regards efficiency, the amount being entirely dependent upon the closeness of the regulation of the engine. With first-class multiple crank engines with liberal flywheel capacity, the loss in efficiency would rarely, he thought, exceed 1 per cent. But unless a fair engine specification was rigidly adhered to, it might often run to 2 or 3 per cent. He also thought the triple concentric cables were troublesome in the balancing of the voltage. Symmetrically arranged, three-core cables were more satisfactory, but instead of employing one three-core cable to transmit the current, it could with advantage be divided up into two or three cables in multiple. He recalled cases with troublesome engine speed and no corrective devices, where attempts to run two rotaries in parallel had often resulted in failure when only one three-core cable was in service, although this was of ample capacity. The throwing in parallel of another similar cable permitted the parallel running of the rotaries. The main argument in favour of rotatory converters and static transformers, as compared with the motor generator method, was based upon the lower first cost and the higher combined efficiencies. As an example in the Blackrock sub-station of the Dublin electric tramways, where 30 periods 200 kilowatt rotatory converters were fed by oil circulation transformers, the combined efficiency being 92 per cent. at full load and 91 per cent. at half-load, the cost of the equivalent motor generator set would have exceeded that of the combined cost of rotary and transformers by 10 per cent., and its combined efficiency would have been 85 per cent. at full load and 82 per cent. at half-load. But the very high efficiency obtained in Dublin involved higher cost, (particularly as regards the static transformers) than in another case where air blast transformers were used. Here, at an efficiency of 90 per cent. at full load, the combined cost was only 80 as against 100 for the Dublin sets and 110 for the motor generator sets, However, the motor generator was much more flexible than the rotatory converter as regards independent control of the alternate-current phase relations and the continuous-current voltage and output conditions. The range of adjustment of the commutator voltage in the case of the rotary converter was only obtainable by virtue of lagging and leading currents, or else by reverting to auxiliary boosters or to variable-ratio transformers. All such additional appliances tended to cut down the margin of advantage. Long ago he had investigated the matter of the resultant C^2R values in the armature conductors of a three-phase rotary, following practically the same plan as that adopted by the author, but he had also deduced values for other power factors. The results were: for power-factor unity the resultant C^2R was 58 per cent. of that of the same armature in a continuous-current generator of the same output; for a power factor of 0·87, it was 85 per cent.; for 0·5, 37·5 per cent.; and for 0, 0 per cent. These results were on the assumption of 100 per cent. conversion efficiency. He did not think that sufficient emphasis had been laid upon the fact set forth by Steinmetz and Kapp, that in six-phase rotaries the alternating and continuous-currents in the armature cancel each other so much more effectually, and, while as regards armature heating the three-phase rotatory converter had an advantage of 34 per cent. over the same machine operating as a continuous-current generator, the corresponding advantage possessed by the six-phase rotary was no less than 95 per cent., *i.e.*, almost twice the output must be taken from it for equal armature heating. Nor did it introduce much complication. The high-potential circuits, both line and static transformers, remained exactly the same as for three-phase. The only difference was that all secondary terminals were carried in the sub-station from the secondary terminals of the three-phase transformers to collector ring on the rotary converter. In such a case one would arrange not to have any switches in the low-tension alternating-current circuits, thus avoiding complications at the switchboard. In rotary converters the current was incompletely commutated. In a certain plant once he interposed the 300-volt coil of an 80 kilowatt transformer between the negative 'bus bar and the rail, and had the current been really uniform there would have been but a trifling drop, say, 5 volts, through the ohmic resistance of the transformer coil. But there was a very considerable drop across it. The interposition of the resistance of this coil reduced the telephonic disturbances on a branch of the telephone system which used a ground return, hence before its interpolation the pulsation of the current was probably much more marked. When this rotary converter was subsequently got into thorough working order the telephonic disturbances on this grounded circuit became so slight as to cause no comment. He thought the 16-pole 600-kilowatt machine, running at 188 revolutions per minute, at the Schenectady works, must be a quarter-phase rotary and not a three-phaser. This showed the ratio conversion to have been in accordance with general practice.

* Mr. W. M. MORDEY mentioned that he had seen many converters working in America and on the Continent, and had observed an interesting fact with regard to the hunting. It was considerably lessened if not done away with altogether by putting a short-circuited coil of copper round the field. This was an old method for various purposes, but he thought it was interesting to mention it on account of what Mr. Field had said about the alternative difficulties of laminated poles which did not check see-sawing, and solid poles which checked see-sawing but wasted power. Obviously, if eddy currents were useful for steadying purposes, they should be applied to give the greatest effect with the least loss; they should surround the core, and should have copper circuits provided for them instead of iron. The right way would seem to be to use laminated poles with a closed copper circuit round them. The author, who was a master of exposition, had given an admirably simple and clear treatment of a very difficult subject.

* Mr. A. J. LAWSON referred to the see-sawing of rotatory converters, and said that two years ago he went over the Tivoli-Rome transmission installation, and Prof. Mengarini had told him that he had a great difficulty with any converter of over 60-kilowatt output, and he strongly recommended for tramway work the use of motor generators. Since then he believed these had been put in for the larger sizes. A few months ago he went over the Paderno-Milan installation, where three-phase generators were used at a distance of 21 miles from the station, and in the old Edison stations they were now putting in motor generators to transform both from the high-voltage three-phase to 220 volts for the Edison three-wire system for lighting, and also for the 500-volt tramway system. There the motor generators had been used exclusively, and they had a flexibility with motor generators that could not be obtained with rotary converters. At this latter installation the machines had been tested up to 20,800 volts, and for the last three months had been working at 13,500 volts without any step up transformers, and as these voltages could be taken out of the machines they could also be put into them and the continuous current machines kept quite independent. He would like to know if Prof. Thompson had got at his fingers' ends the relative costs and efficiencies of motor generators and rotary converters of sizes from 200 kilowatts and upwards.

* Prof. CARUS-WILSON said it was well-known that the load at which an alternate-current motor, running synchronously, fell out of step depended very largely upon the heating of the armature. Referring to Mr. Field's experience with a short circuit on a converter, he (Prof. Carus-Wilson) ventured to predict that if it had been a synchronising motor running a direct-current generator, the synchronous motor would have fallen out of step. He was inclined to think that the satisfactory result must have been due to the fact that, although the current output on the direct-current side was so enormous, yet the C^2R losses in the armature were reduced in virtue of what they had been hearing from the author. It appeared to him that the inertia of the rotating part of the converter must play a very important part in all the functions that such a machine was called upon to perform. It seemed to him important in the design to consider the effect of increasing the moment of inertia of the armature. Incidentally, it occurred to him that the hunting difficulty might be met by a similar remedy. In the matter of reaction, he thought the rotatory converter held an immense advantage over the dynamotor method. In the case of a rotatory transformer, fed from an alternate set and delivering direct current, the energy component which would be in step with the induced volts of the machine would tend only to distort and was unable to magnetise or to demagnetise. On the other hand, the wattless component of the current tended to magnetise or demagnetise. It followed, therefore, that since the distorting component was the only one that could give trouble from the sparking point of view, this was the only one they need discuss in considering the question of reaction. If they had an armature with two windings—a primary and a secondary—and if there was absolutely no torque loss in the armature, it followed that the distorting reaction due to the energy component must be equal and opposite in both sides of the armature. It followed, therefore, that whatever transformation they were having, that the distorting component of the current in the two sides of the armature must be absolutely equal and opposite—that was to say, there was no resultant distorting action in a rotatory converter which had absolutely no torque loss. If, however, there was a torque loss—as, of course, in practice there always would be—then the amount of that torque loss would be a measure of the tendency to distort the field, and, therefore, a measure of the tendency to spark. Mr. Steinmetz, in a Paper some two years ago, proved mathematically that in a rotatory transformer, in which there was absolutely no torque loss, the reaction components of the two sides were absolutely equal, and there was no reacting tendency whatever. His own reasoning also showed that the reaction in a rotatory transformer only depended upon the amount of current required to overcome the torque loss in the machine, and it appeared to him that, if on that account alone, the rotatory converter had a great advantage over the dynamotor method.

*Mr. E. KILBURN SCOTT expressed a doubt as to whether rotatory converters were really necessary for railway work. For instance, on the Gornergrat and Jungfrau railways three-phase motors were used on the locomotives. The inclines were 20 per cent. and 25 per cent.—a sufficient answer to the query, "Has the three-phase motor enough torque to work heavy gradients?" The question of control was another point which had been queried and upon this he had received a letter from Mr. C. E. L. Brown, confirming his (Mr. Scott's) opinion that the Central London Railway might very well have been worked by three-phase locomotives and the rotatory converters dispensed with altogether.

*Mr. EUSTACE THOMAS referred to Mr. Esson's remarks that in some cases converters had been taken out and replaced by motor generators. He

Digitized by Google

thought that in some of these cases it would be found that they were single phase converters rather than three-phase or quarter-phase. This was partly due to the fact that the torque is quite uniform in the case of three or four-phase machines, but not with single-phase supply. Consequently, they had set up a varying torque which was likely to give trouble. Again there was a great deal of difference in the heating in the two cases. He quoted tests: a rotatory converter both as a three-phase and single-phase machine, and showed that as a single-phase converter the total amount of power got out of it for a given amount of heating was only 55 per cent. to 58 per cent. of the power that could be taken from it as a three-phase converter. It was an actual fact that it was easy to correct any trouble from hunting. The causes were fairly well understood. With regard to the question of reaction, he said there was no resultant reaction in a three-phase converter when it was adjusted for minimum input of current and when the losses were comparatively small—that was to say, the armature reaction of the three-phase part balanced exactly and overlay the armature reaction on the continuous-current side; but, as soon as the field was under or over-excited, then immediately lagging or leading currents came in and produced armature reaction. Unless there were in the circuit a sufficient amount of auxiliary reactance it was necessary to obtain voltage regulation to make the current lag or lead by a rather considerable amount, necessitating correspondingly heavy series compounding coils. In practice, this was no difficulty. For instance, after consideration it had been decided to work street railways in New York electrically, and to use rotary converters and three-phase transmission. There were to be six or more generators of 3,500 kilowatt capacity, and the distribution would take place through rotary converters. From practical experience it had been found—in the matter of regulation—that for a given load with rotaries and generators in circuit, the load might vary from nothing up to a considerable overload with the voltage on the continuous current side varying from 2 per cent. to 4 per cent. The question of the armature action of rotary converters was rather an interesting one in connection with sparking on the commutator side. The brushes were, as the author had said, almost always fixed dead at the neutral point; in some cases a slight lead might be given. On account of the balancing of the reactions on the two sides, the field was practically unaltered over the pole tips. The fact that at the same time one could get sparkless commutation made it very clear that we have to depend on something other than a reversing field. The rotary converter, and still more the railway generator, shewed clearly that sparkless commutation must be obtained from some quite different cause. Comparing two and three-phase converters, he said that although both types would give uniform turning moment on the armature of the rotary converter, yet there was a strong advantage in favour of three-phase in transmission lines. For an equal amount of energy transmitted they would only have to employ about three-quarters the amount of copper in three-phase that they would in two-phase, and more than that, only three conductors would have to be insulated instead of four. This meant that the total cost would be correspondingly diminished.

*Prof. SILVANUS P. THOMPSON, replying, thanked Mr. Thomas for the very valuable information he had given them. He was not disposed to question Mr. Scott's accuracy in thinking that it might have been an advantage in the Central London Railway to do without any converters, but that was not the point of the Paper. Prof. Carus-Wilson had drawn their attention to a very important point in saying that the limiting load of a synchronous motor would depend upon the heating of the armature, and at the same time had emphasised that the moment of inertia was of importance. It was of importance in the case of single-phase converters, but he doubted whether it came in very much in the case of two or three-phase, for the simple reason that their torques were so very uniform. The argument that Steinmetz put forward some years ago was all right. In Prof. Carus-Wilson's simple form it was this: if there was no heating loss in the armature the two torques must be equal, and, therefore, the distortions would wipe one another out. That was literally so, provided the ampere-turns of the two sides at every moment were equal. If there were no losses, both torques must be equal on the average. But, in the case of a single-phase machine, they were varying from moment to moment, and there certainly would be armature reactions from moment to moment. Mr. Lawson had referred to the Tivoli-Rome transmission installation, where motor generators were employed to feed the tramways. The alternate-current generator at Tivoli was single-phase, and single-phase converters were admittedly bad on account of the armature reactions and trouble from sparking. It was a curious fact that the firm who supplied these machines had altered their design several times since. Probably, if the whole of that station had to be designed over again, they would put in either two or three-phase at Tivoli and use converters at Rome. Mr. Mordey had referred to the advantage of using a short-circuited copper winding round the poles. Certainly that was a great advantage in some cases; and not for converters only, but for alternate-current machines of several types when running in parallel. He did not want to dispute at all the emphasis which Mr. Hobart placed upon the necessity of having the engine power regular if the machines were to keep in step, for they must remember that the engine power transformed itself through the generator and through the line and through the stationary transformer. Mr. Hobart had referred to the great advantage of using six-phase converters. As was pointed out by Mr. Kapp and Mr. Steinmetz, this certainly was an admirable thing, and could be used very easily in those cases where a stationary transformer was used to transform down the voltage from high voltage transmission. He objected to the misleading use of the adjective "static" for "stationary." In efficiency, a four-phase converter was better than a three, and a three better than a thing that had two slip rings, while a six-phase was better still. For a given power it gave less heating, or for a given limit of heating it might be used to transmit a larger amount of power. He thought Mr. Field's suggestion of using leakage transformers for regulating the voltage ratio was rather a lame solution. In reply to Mr. Swinburne's insinuation that he had changed the English language, he ventured to challenge him or anyone else to produce a standard English dictionary in which there was such a word as "rotary." There had been a syllable cut out of the word, which he did not think improved it, and it did not add dignity or literary (or should he say "litary") form to any communication that might be written in such abbreviated language.

LONG-DISTANCE TRANSMISSION OF ELECTRIC POWER.*

BY PROF. GEORGE FORBES, F.R.S., M.INST.C.E.

This subject has been much talked about, but little has been done, and even at this moment there are few people who realise what a vast field there is in this way for investment of capital on a sound commercial basis. Hitherto people have been appalled at the capital required for copper conductors. In the present Paper I bring forward nothing new. I use the methods which have been used for shorter distances; and I do not propose to suggest the use of electric pressures which have hitherto been considered unattainable. In all cases it is assumed that the power is generated by a waterfall driving a turbine which rotates a dynamo machine. The electric pressure may be raised by transformers. It is then carried by bare copper conductors to a point perhaps hundreds of miles distant; the pressures may there be lowered. The current is then passed through an electric motor which drives stamps, or mills, or pumps, or hoists, &c. During the progress of the electric works at Niagara Falls, attention was much given to the economic problems involved in the transmission of electric energy to a distance. But in that case clearly the following financial conclusion ruled the conditions:—It is always more profitable to bring the works requiring power to the electric source of power than to transmit the power to a distance *provided*—and in most schemes this is a large IF—you can find consumers to come to your locality. At Niagara this seemed likely, and, consequently, distance transmission beyond 25 miles was considered undesirable in the first instance.

Of all industries to which it is applicable, gold mining is the one which has come mostly to my notice as wanting a continuous supply of power day and night, and often without any economical means of getting it except by electric transmission. In these cases it will often be profitable to the gold miner to pay a high price for his power. The distances which I have had to deal with go up to 250 miles in India, New Zealand, and Egypt, and if the Rhodesia mines show generally such returns as the Geelong and Selukive mines have done, I have shown that the power of the Victoria Falls may be economically transmitted in some cases to 500 miles, and pay well.

In 1893, I sat on a committee appointed by the Indian Government to see whether the water power, incidentally created by the Periyar irrigation works, could be used for making aluminium electrically out of the corundum found in the neighbourhood, and for other purposes. We found that power could be generated very cheaply, but that the corundum was not suitable, and no other important demands for power were brought to our notice. Years afterwards, I found that the Mysore, Kolar, and other gold mines could easily be reached by the power, and save great cost in coal. Here we have a transmission of 250 miles which will pay well if the mines are likely to continue producing gold as they have done.

Another specially favourable case of gold mines is in New Zealand, in the North Island. The Waihi mines already work their mills by electrical and water power, but there is no adequate supply of water in summer. At many of the other mines there are no roads, and power cannot be obtained. In 1896, I was asked to explore the Waikato River, in order to find the best site for developing power to be transmitted to all the gold mines on the Coromandel Peninsula, near Auckland. I finally settled on the Haka Falls, near the centre of the island, with a transmission line of from 180 to 250 miles, 20,000 H.P. being generated to supply not only all the gold mines but every freezing works and factory on the North Island. I spent six weeks on the survey of sites for the works, and furnished plans which would already be executed, except for what I must call the dog-in-the-manger policy of the Government. The site was peculiarly favourable. To take another case of gold-mining. I was engaged in 1895-96 on a project without water power and a transmission of 300 miles as a maximum. The Coolgardie gold fields are so far from a port that coal is very expensive, and water for the boilers could hardly be obtained. I found that it was actually more economical to generate power by steam engines at the coast, where coal and water were available, and to transmit power all the distance electrically, rather than to transport coal which was otherwise a necessity in all cases as well as water in many cases. In this case the miners were prepared to pay as much as £180 per annum for the horse-power.

* Abstract of a Paper read before the Society of Arts, November 23, 1898.

Digitized by Google

In 1894, before I had completed the first electric works at Niagara, I was asked by letter from Johannesburg whether it would be possible to transmit power from the Victoria Falls, on the Zambesi, to all the gold mines in Rhodesia, varying from 350 to 500 miles distance. I had been supplied with maps and costs of fuel, &c., and in a short time I found, to my astonishment, that if the facts were as stated, the scheme was financially and electrically a sound one. I was assured that at least 10,000 H.P. would be required at the mines, and that from £70 to £100 per annum would readily be paid for the horse-power. Upon this I was asked to go to South Africa to negotiate with Mr. Cecil Rhodes and Dr. Jameson for a concession. They both appreciated the value of the enterprise to the country, and prepared a draft of the concession, which was only awaiting the sanction of the Chartered Company's Board when the Jameson raid and the Matabele rising closed negotiations. Here is a case where, if there be really good gold mines, it will pay handsomely to transmit electric energy a distance of 500 miles, provided the surveys of the Falls prove as satisfactory as the photographs do, and provided the fever is not an insurmountable obstacle.

At this stage let me point out to those unacquainted with the difficulty of obtaining power at some gold mines that £100 per annum for each horse-power continuously delivered would readily be paid in many cases. Broadly speaking, the power required for rock breakers, stamps, &c., may be taken as being such that 1 H.P. mills 1 ton of ore per day; the value of the gold is, say, £3 or more per ton in a rich mine. I am not speaking of soft conglomerate like the Rand ore, where 1 H.P. mills 2 or 3 tons per day, but hard quartz. Now, when I speak of £100 per annum for a horse-power; this, at the rate of 1 ton a day, means 5s. 5d. per ton of ore for milling expenses. There are plenty of places where they would pay double this.

But while I expect that gold mining is the principal industry to be benefited, there are many others, the chief requisite being a continuous demand for power day and night. This is met by electro-metallurgical processes, but these can generally be brought to the power. It also includes irrigation, which in some countries wants power day and night, and, to a certain extent, throughout the year. The quantity of water pumped does not need to be perfectly constant, and this enables intermittent demands for lighting, railways and factories, to be met by slight variations in the pumping. Thus the plant is always fully at work and earning its dividend. In speaking these words I am naturally thinking of the utilisation of the Nile cataracts, upon which I have been engaged during the years 1897-8. My report on this subject is in the hands of the Egyptian Government, and is their property; but I am not divulging secrets when I tell you that the electric lighting of Cairo could be done cheaper by power generated at the First Cataract than by steam engines at Cairo. The distance is 400 miles as the crow flies. Do not imagine that I propose lighting Cairo immediately in this way. The Government has far more important uses for the power, not only in the irrigation of the country as it is, but still more for the perennial irrigation which will be so much extended when the great reservoir designed by Mr. Willcocks, Sir William Garstin and Sir Benjamin Baker shall be completed by Mr. John Aird. You may take it as certain that before long the cataracts will be harnessed and forced to assist in developing not only Egypt proper, but the Sudan, and specially the Dongola province up to the Fourth Cataract, which, with efficient irrigation, may become the most fertile country in the world.

Higher up the Nile, I have not travelled or made surveys, but I notice that Sir William Garstin is undertaking a journey to Khartum and the Blue and White Niles to determine the value of the country there. A time will doubtless come when the Murchison and Ripon Falls will also be turned to account.

In 1882, at Munich, Marcel Desprez earned great credit for transmitting electric power 35 miles and getting a return of 25 per cent. But, in 1891, 70 per cent. efficiency was obtained between Lanffen and Frankfort, the distance being 108 miles. Only one difference between short transmissions and the 108 miles from Lanffen to Frankfort was found to exist and it had been anticipated by me in preparing the Niagara works. In 1892, I laid it down as essential for the works at Niagara, in order to be prepared for long distance work and for other reasons, that the frequency of the alternations should be as low as the construction of a good dynamo would warrant. In 1894, the tests at Lanffen-Frankfort were published, showing that without this low frequency no good efficiency could be got from the long distance power transmission owing to the great self-induction of the line.

All engineers will agree as to what is the principal item of expenditure, viz., the cost of copper under the conditions of existing practice. Improvements may reduce this cost, but cannot increase it; hence the financier may be very sure of the data of expense, and if he can be equally well assured of the data of revenue, he has before him everything required for forming a sound judgment. Let us take three cases.

1. Suppose a water-power is utilised for distant transmission of 200 miles to a gold mine where transport is difficult and the ore rich. Suppose that the miners are ready to pay £100 per annum for each horse-power delivered continuously to the stamps, &c.—I am taking what may be looked upon by some as an extreme case, but there are many such places in the world—suppose that it is a gold field employing only 1,000 horse-power continuously, the gross income is then £100,000 per annum. This is a large sum, and will warrant a very large capital expenditure. Now if it is a case in which 20,000 volts electric pressure may be used, less than 900 tons of copper is required, after 50 per cent. has been added for self-induction, giving an inefficiency (inverse of efficiency) of only 1·4. Thus, 1,400 H.P. will have to be generated at the waterfall end of the transmission line for 1,000 H.P. delivered at the other end—the gold mine. The hydraulic and electric machinery are not likely in a favourable case, even with costly transport, to exceed £14,000. The working expenses are small, and clearly the great thing to be considered is the cost of copper. If transport is costly, this might amount to £80 per ton of copper laid, or £72,000. Very likely the whole cost would be under £100,000, which, with a maximum possible annual expenditure of £20,000, would produce a revenue of £80,000 per annum or 80 per cent. I am sure that actual cases exist where this might be done.

2. If the distance were 400 miles, all other things remaining the same, the only serious difference is in the cost of copper, which rises to £288,000; and taking £32,000 for the other expenses, the capital expenditure is £320,000. If the annual expenses were £20,000, which seems impossible, the net income is £80,000, or 25 per cent.

3. Suppose the distance still 400 miles, and all other things remaining the same, but only £50 being paid per annum for the horse-power; here we have still £320,000 of capital expenditure, and a net income of £30,000 for 1,000 H.P. delivered, or 9 per cent.

Of course, it understood that while cases can occur where these figures apply, each case must be examined on its own merits. Looking at the last case quoted, the delivery of 1,000 H.P. at 400 miles, using 20,000 volts (or 200 miles with 10,000 volts), the financier would say 9 per cent. was not good enough for such a venture. I will now show how he may get 40 per cent., using the same machinery, the same copper, and the same annual expenses.

I have now the pleasure to lay before you a simple financial transaction which copper merchants or others would willingly make, and which may avoid the huge capital hitherto required by those who transmit the power, and will increase the dividends on money spent on the transmission. What I propose is to divide the capital account into two parts—ordinary stock, which may be looked upon as speculative; and bonds on the copper, which would be as sound an investment as could be desired. Taking the last case mentioned, the capital charges are—

3,600 tons of copper at the extreme value of £75 a ton	£270,000	
Putting it in place at £5 a ton	18,000	
		£288,000
Hydraulic and electric machinery, &c.		32,000
Total capital required		£320,000

Most of this capital is required for copper, which may be taken away if the company fails, and is an absolutely safe security.

The value of the copper is	£270,000
Cost of removal (uncalled capital)	18,000

On the £270,000 a mortgage may be raised, and 4 per cent. ought to cover the chances of a change of market value. Thus we have—

Annual payment on mortgage	£10,800

All we have done is to raise a mortgage on the best possible security. This might be done by the copper companies, who often have too much material in stock not paying interest, or the money could easily be obtained from independent capitalists. Let us now see what difference this has made upon the balance-sheet. The capital charges are—

Putting copper in place		£18,000
Hydraulic and electric machinery		32,000
		£50,000
Annual gross receipts—1,000 H.P. at £50		£50,000
Less annual expenses	£20,000	
Mortgage on copper	10,800	
		30,800
Annual net receipts		£19,200

or almost 40 per cent.

By this simple transaction we reduce the total capital required by the transmitters of power from £320,000 to £50,000 for 1,000 H.P. delivered, and we have increased the rate of interest from 9 per cent. to 40 per cent., which ought to satisfy most people. This scheme I have laid before the manager of one of our largest copper companies, and he entirely approved of the general lines.

Before leaving this part of the subject, I wish to make it quite clear that none of the figures which I have given up to the present must be taken as applicable to every case that may arise. The costs used in the above calculation are over the mark for the most favourable cases, and the cost of copper is also too high. All that I have tried to make clear is that if there be a large and continuous demand for the power, and if the value of the mechanical power to the gold miner or others is great, the distance to which it can be transmitted with financial success is not limited to a few hundred miles.

I feel some diffidence in laying before you the following methods because there is nothing new in the results, and all the results can be obtained by the ordinary methods. They have, however, been invaluable to myself. These methods are particularly useful for getting out preliminary estimates quickly. Here let me say that in all preliminary work on the cost of long conductor lines, I never take notice of the resistance of the conductor, nor of the value of the current. I deal only with the current density, and loss of volts. It is the same thing under a different name. But it is what you want. Again, I never use, in calculations for my own use, the efficiency of the conductor system. It is far more convenient to use the inefficiency, or the reciprocal of the efficiency, which is also the horse-power put into the generating end of the line to deliver one horse-power at the other end. I give you these suggestions for what they may be worth as the result of long experience.

I suppose everyone present is aware of the fact that if you had a case where the power cost absolutely nothing, you would use the least copper and have the cheapest arrangement, with an inefficiency of 2, *i.e.*, an efficiency of 50 per cent., or 2 H.P. generated for each horse-power delivered. If you make the current density either greater or less than what is required to produce this inefficiency then you have to use more copper to deliver the same quantity of power. Fig. 1 shows this very well, and a study of it is interesting. This figure shows the weight of copper required per horse-power delivered at a distance of 100 miles at 10,000 volts, or 150 miles with 15,000 volts, or 200 miles with 20,000 volts. It is drawn for the simplest case of continuous current, to which corrections only for temperature and sag have to be made. It is equally applicable to a single-phase or two-phase alternating transmission to 100 miles at 10,000 effective volts; or at 5,000 effective volts from any wire to the middle of the electric system, or to three-phase transmission to 100 miles at 5,000 effective volts from any wire to the middle of the electric system. But with alternating current corrections must be made for self-induction and capacity.

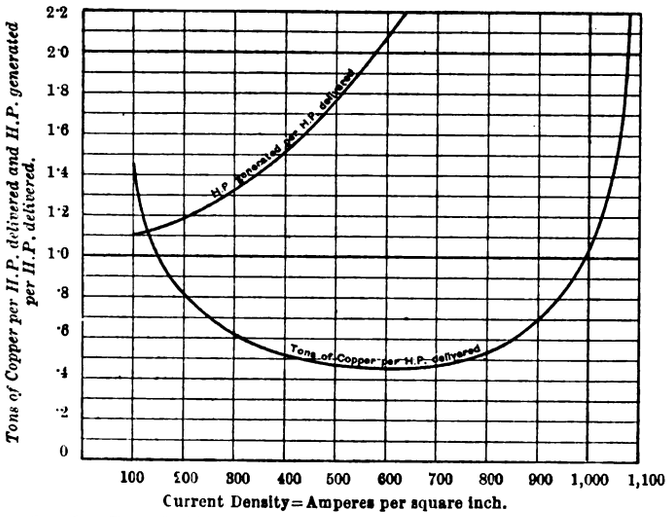

FIG. 1.—Electric Transmission Curve for 100 miles at 10,000 volts Continuous Current.

The same remarks apply to the meaning of the voltage of the line in all the curves and tables referred to. They are worked out for continuous current, and for any other system the engineer must add the usual corrections.

Another curve may be drawn showing the inefficiency at each current density. This curve constantly rises, *i.e.*, the greater the current density, the greater is the inefficiency. Now from these two curves we can deduce a third curve, which is the one which I find gives one in a few minutes all the main facts one wants for any horse-power to be delivered to any distance at any initial volts. This curve gives the tons of copper per horse-power delivered at 100 miles with 10,000 volts, continuous current, in terms of the horse-power generated per horse-power delivered. Measuring along a horizontal line, you get the inefficiency, *i.e.*, the horse-power generated for each horse-power delivered; and measuring vertically you get the corresponding tons of copper required for each horse-power delivered at a distance of 100 miles. The curve is also marked with figures to show the current density, in amperes per square inch section of copper. I never travel a day without this curve in my pocket.

This curve is correct for 100 miles and 10,000 volts, or for any other case where the volts = 100 times the miles. The curve shows you, for example, that for an inefficiency of 1½ you require a current density of 387 amperes per square inch, and 0·55 tons of copper. And thus current density and weight of copper per horse-power is the same, whether you use 10,000 volts at 100 miles or 100 volts at 1 mile. For any other volts and distance in miles, V and M, you divide the volts by the miles and get $\frac{V}{M}$; then $\frac{V}{100M} = D$, the multiplier for the current density, and $\left(\frac{V}{100M}\right)^2 = T$ the divisor, for the tons of copper per horse-power.

As an example, 15,000 volts and 300 miles. Here $D = \frac{15{,}000}{100 \times 300} = \frac{1}{2}$. Hence for an inefficiency as above of 1½, the current density will be ½ × 387 = 198. The tons of copper per horse-power will be $\frac{0{\cdot}55}{(\frac{1}{2})^2}$ = 2·20 tons.

Now let me show another use of the curve. Suppose we capitalise the cost of running the generating station, and add to it the cost of the generating works, and divide by the horse-power, we have then the capitalised value of 1 H.P. generated. I will call it for short the value of 1 H.P. generated. We also know the cost of one ton of copper. Divide the value of the horse-power by the value of the ton of copper, and draw a line across the axes so that it cuts the axes in that ratio. Draw a line parallel to this and touching the curve. This gives you, according to Lord Kelvin's law (as modified by Ayrton and Perry), the point of maximum economy giving directly the inefficiency, the tons of copper per horse-power and the current density. Thus on the curve two examples are shown, one where the value of 1 H.P. is four times that of a ton of copper. In this case the greatest economy is got by an inefficiency of 1·18, a current density of 180 amperes per square inch, and 0·91 tons of copper per horse-power delivered at 100 miles distance, the initial pressure being 10,000 volts.

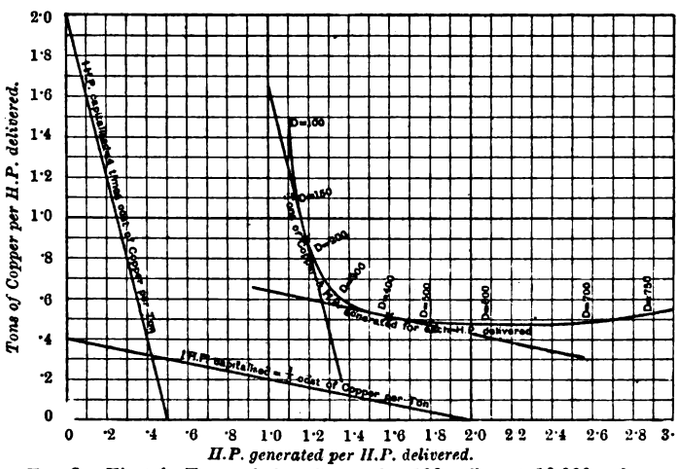

FIG. 2.—Electric Transmission Curve for 100 miles at 10,000 volts Continuous Current.
D = Current Density = Amperes per square inch.
For V volts and M miles multiply the weight of copper by $\frac{M^2}{10{,}000\ V^2}$.

Another example is shown on the curve where the horse-power is one-fifth of the cost of a ton of copper. The resulting values are seen directly to be: inefficiency = 1·58; current density = 420; copper = 0·51 tons.

To do this for other values of T, $\left[T = \left(\frac{100\,M}{V}\right)^2\right]$, you must divide the value of the horse-power by T. Measure this distance vertically by the unit on the vertical scale or by fractions of these units, and measure the cost of a ton of copper horizontally by the unit on the horizontal scale or by the same fraction as before of that unit. Join the two points by a line and draw a parallel line touching the curve at the point of maximum economy.

But we can do more than this. Divide the tons of copper per horse-power by 18 times the distance in miles, and you get the sectional area in square inches of the conductors (go and return) per horse-power. Multiply this by the total horse-power to be delivered, and you get the size of your conductors.

N.B.—Remember that this is all worked out for continuous current, and must be corrected for other systems as well as for temperature and sag.

Digitized by Google

Some people prefer to work by tables instead of by curves, so I will put down the readings of the curve which we have just been discussing. For ordinary work the following is sufficient :—

Inefficiency.	Tons copper per H.P.	Current density.	Inefficiency.	Tons copper per H.P.	Current density.
1·10	0·86	190	1·70	0·49	475
1·30	0·66	266	1·80	0·48	510
1·40	0·58	330	1·90	0·472	545
1·50	0·55	387	2·00	0·470	574
1·60	0·51	432			

In most practical cases, however, the economical inefficiency for long distance transmission lies between 1·20 and 150. The following table gives closer values over this range :—

Inefficiency.	Tons.	Density.	Inefficiency.	Tons.	Density.
1·20	0·86	190	1·36	0·60	306
1·22	0·80	207	1·38	0·59	319
1·24	0·76	221	1·40	0·58	330
1·26	0·72	236	1·42	0·57	342
1·28	0·69	250	1·44	0·56	354
1·30	0·66	266	1·46	0·55	365
1·32	0·64	279	1·48	0·54	376
1·34	0·62	292	1·50	0·53	387

From either of these tables, having given the efficiency, to get the density for any volts and distance, multiply the above value by $\frac{V}{100M}$, and to get the tons of copper, divide the above value by $\left(\frac{V}{100M}\right)^2$.

In actual practice I find it far more useful to have the table extended in such a way that an approximate result may be arrived at without any calculation. Three tables are here given. The first gives a reference letter for any volts and distance. In the second and third tables the results we want are found under that reference letter. The second table gives the tons of copper per horse-power delivered, and the third gives the current density for any inefficiency that we may select.

Table I.—*Distance of Volts.*

	Virtual volts between wires.					
1 or two phase	5,000	10,000	15,000	20,000	25,000	30,000

Rules for Using the Tables.

Rule I. *To Find the Reference Letter.*—In Table I., in the column referring to the volts generated, find the approximate distance of transmission in miles. The capital letter at the beginning of the line in which this is found is the reference letter.

Rule II. *To Find the Tons of Copper per Horse-Power Delivered.*—Look along the row in Table II., referring to the reference number, and tons of copper are there given for each inefficiency. The inefficiency being the horse-power generated to deliver the horse-power at the distant point.

Rule III. *To Find the Current Density.*—Table III. gives this in amperes per square inch in the row corresponding to the reference number, and in the column corresponding to the inefficiency chosen.

Rule IV. *To Find the Economical Conditions of Working (Kelvin's Law).*—Divide the capitalised value of 1 H.P. by the cost of 1 ton of copper. Divide this by 10, and call it q. In Table II. look along the row corresponding to the reference letter until the difference between successive numbers is approximately q. The number at the head of that column is the economical inefficiency, the tons are also then given, and the current density is obtained directly in Table III.

Rule V.—*To Find the Total Section (go and return) of all the Transmission Conductors.*—Multiply the tons per horse-power by the total horse-power, and divide by 18 times the distance in miles. This is the result in square inches. Dividing this by the number of conductors gives the sectional area of each.

The only point affecting the cost which has been left to the choice of the engineer is the electric pressure to be used, and every engineer in reporting on a scheme generally gives his reasons for selecting the pressure. In old days the highest pressure for which we could get a guarantee from contractors was used. But the expense of insulation increased so much with increase of pressure that now, as at Rheinfelden, we work to that pressure which is the most economical. Manufacturers will now guarantee any pressure if you will pay for it.

It has been my object to-night to put before engineers some useful rapid methods for arriving, on the ordinary lines of working, at the data for any special case of long distance transmission of power. It has also been my object to show that those who carry out such schemes do not require to be handicapped by the enormous capital which has hitherto been generally considered necessary. Incidentally it would appear that whenever gold mines exist which can afford to pay 5s. or 6s. per ton of ore milled, and if there be good water-power within 400 miles of the mines, it is most probable that it will pay well to transmit the power electrically.

The following is an abstract of the discussion which took place in connection with Prof. Forbes' Paper :—

The CHAIRMAN (Sir John Wolfe Barry) said that Prof. Forbes had brought before them a most suggestive and valuable Paper. One of the great matters which was pressing upon the engineering mind was the conservation of energy, and this might take the form of capturing the power which exists in the clouds and comes from them in the form of rain, or it might be harnessing the winds and making them serve for the "use and convenience of man." Another proposal had been to capture the force which ran to waste in the waves, and before all was the seductive subject of capturing the electricity in the air. The fact of having to pay £100 per horse-power was rather startling to them, but then Prof. Forbes had given figures which showed that the gold-mining industry could afford to pay this amount. We looked to realise a horse-power at something like £5 or £6. A mortgage on a mass of copper in the centre of Africa at 4 per cent. seemed to him somewhat hypothetical. No doubt the value of the copper would be there, but he doubted whether capitalists in London would advance 4 per cent. under these circumstances.

Colonel GOURAUD said that just after the great boom of the Crystal Palace electrical exhibition he, along with others, formed a company with a capital of £1,000,000 sterling with the object of lending money to people who had central station schemes on hand ; but at the end of a year they had been obliged to call a meeting of the shareholders and confess that they had not succeeded in finding a profitable employment for their money, for, said he, as chairman of the company, "We are 10 years ahead of time." With respect to Prof. Forbes' copper proposition, he thought that as there was not a copper market in Central Africa, he should add the cost of copper transportation out and back again in case the project was not successful. Even then, on the figures given in the Paper, the speculation should still be a profitable investment.

Mr. G. L. ADDENBROOKE had been on the Continent and had seen machines in course of manufacture at Messrs. Brown-Boveri and Co.'s works which were going to generate at 13,000 volts without transforming up. In the course of his travels, nothing had struck him so much as the confidence with which foreign capitalists had put large sums of money into water-power transmission schemes. There was a great difference between steam and water-power transmission. With steam, they need only start on a small scale—1,000 H.P., for instance—and in many cases they could wait and see whether they were going to have any return, but in the case of water-power transmission they had to put down their fundamental works on somewhat the same scale as they were going to work. At Rheinfelden, they had put down plant for 25,000 H.P., although only about one quarter of this was at present utilised. They had thus a large amount

Digitized by Google

of capital locked up which certainly was not remunerative at present, but the capitalists had sufficient confidence in the concern to wait until it was so.

Mr. LÉON GASTER mentioned that in Switzerland they were generating by water power at 5,000 volts, and getting 77 per cent. at the end of a line 12½ miles long. He thought the only way to make water power schemes a success was by having very large central stations, from which they could meter out current to small consumers, who would otherwise have to erect small plants of their own.

Mr. W. M. MORDEY thought the question was a commercial one, and not a technical one. He did not mean to say that there were not many interesting technical considerations in the Paper itself, but the great value of it was that it did not contain any reference to technical difficulties, and this, he thought, was a significant thing. By offering 40 per cent profit Prof. Forbes should be able to make the mouths of capitalists water to such an extent as to get a water power of great dimensions.

CORRESPONDENCE.

ELECTRIC CANAL HAULAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of October 21st you published a Paper by Mr. Allen, and in that of November 4th a letter of criticism by Monsieur F. Galliot, and a reply thereto from Mr. Allen in your issue of November 18th. A perusal of the latter would lead many readers to suppose that the gentlemen named in the Paper and letter had quite solved the problem of electric canal haulage in this country. Will you please permit me to point out that the system of procedure I have devised, in conjunction with Mr. W. E. Kenway and his invention of overhead conductors, has some claim to the attention of those interested in the improvement of our canal haulage?

We dispense with the use of hauling ropes entirely, tow-path motors or aërial railways. Our conductors are mounted on Norway poles along the present tow-paths, and there is no interference with the fair way of the canal. Craft with masts or sails can proceed along the waterways as usual. We place our propelling device (in which the electric current is the source of power) on a light framework on any canal boat, and the whole contrivance may be unshipped when necessary.

Our joint invention has resulted from a study of the requirements of the complex Midland canal system.—Yours, &c.,

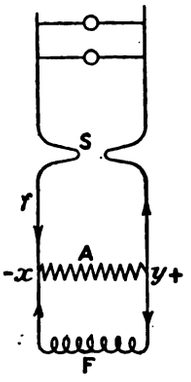
Birmingham, Nov. 30. T. VAUGHAN HUGHES.

THE BRIGHTON BREAKDOWN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Quin's interesting letter in *The Electrician* of last week draws attention once again to the Brighton breakdown, and to the experience, apparently not very rare, that severe external short circuits may demagnetise or even reversely magnetise the fields of shunt dynamos supplying that circuit. It seems to be of some interest to look at the possible causes of this effect a little more closely. The following is a suggestion which may or may not have been made before. Let A be the armature of a shunt machine supplying a feeder F, and S, a place where a sudden short circuit occurs which causes a momentary very heavy current to be taken from the machine. The circuit A F S is a circuit of very low resistance, but one having considerable inductance and not altogether negligible capacity. Hence the establishment or rupture of a sudden heavy "short" at S will set up in this circuit electrical oscillations. Accordingly, at the shunt-field terminals x y rapid alternations of potential are established super-imposed on the normal potential difference due to armature E.M.F.

The effect of the heavy current taken out of the machine is to enormously increase for the moment armature the reaction, and this alone tends to demagnetise the fields, whilst at the same time the drop in armature E.M.F. will reduce the normal shunt current. Hence the rapid decadent oscillations of potential at x y will send oscillatory currents through the shunt which may overpower the normal magnetising current, and are exactly of the character required to demagnetise the iron. The reverse magnetisation sometimes finally left may be due to the final rupture of the short-circuit creating a momentary increased rush of current through the armature (due to inductance), causing the potential at x to rise above that at y, and sending, therefore, a wave of current in the reverse direction to the normal one through the shunt. These current changes are so rapid that no maximum or minimum cut-out which depends on the magnetisation of iron has time to act. One remedy which might be effective would be the separate excitation of the fields, not from the main omnibus bars, but from a separate exciter plant, preferably including a storage battery. Conditions of economical working may, however, prevent the adoption of this drastic remedy. It is easy to see in the above theory why compounding the fields is at least a partial

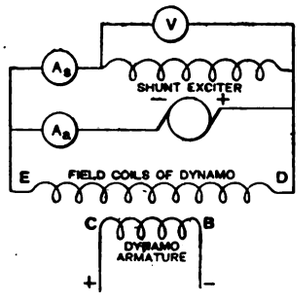


remedy for the mischief, but it is not easy to see any effective remedy other than that of separating entirely the shunt field circuits from the omnibus bars and separately exciting the fields.—Yours, &c., J. A. FLEMING.

University College, London, Dec. 5.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The very interesting account given in your last issue by Mr. Quin of his experience of the action of a short-circuit across the terminals of a separately-excited dynamo shows that the "transformer" effect, to which I called attention in my note on shunt dynamos in parallel, is of such magnitude, that as I suggested might be the case, it can, not only reduce the current in the shunt circuit in parallel, but may actually reverse it. The diagram, which I gave of the connections



made in my experiment, and which I repeat with slight modification here, gives precisely the connections which would exist in a dynamo separately excited by a shunt machine. The action is as follows:—

1. The sudden increase of current from B to C in the armature of the short-circuited dynamo suddenly removes lines of magnetic force from its field coils (due to the lead on the dynamo brushes), and, therefore, sets up an E.M.F. in these coils such as to drive the current in them from D to E—that is, increases the original exciting current momentarily.

2. But as the field coil is now a *source* of E.M.F., owing to the lines removed from it, it must be remembered that the point of highest potential due to this E.M.F. will be at the end E.

3. If the short-circuit current has been sufficiently large in the dynamo, the E.M.F. set up, as described in 2, will (*a*) increase the current through the exciter armature, and (*b*) decrease its field current or even reverse it.

4. The reversed current in the exciter shunt reverses the polarity of the exciter which (as the "transformer" E.M.F.

Digitized by Google

in the field coils of the dynamo is only momentary), in its turn, reverses the field of the dynamo and therefore its polarity.

There are evidently at least two methods of avoiding this trouble, viz. :—To use separately excited machines, the armatures in parallel and protected by maximum, and reverse current cut-outs and the fields excited either :—

1. By secondary batteries ; or
2. By a series-wound dynamo.

In each case, of course, a regulating rheostat would be placed in the dynamo field coils.

I do not know whether any stations are run with machines in parallel and separately excited in this manner, but, if so, it would be of interest to know whether they have ever experienced the trouble described by Mr. Quin or have had any breakdown of the character which occurred at Brighton.

Mr. Quin does not state whether the case he describes, of an earth on an armature setting up a pulsating current has been actually observed in practice : it is certainly possible, and, as he points out, no system of cut-outs would appear to satisfactorily guard an armature so earthed from the possibility of burning out. If, however, it were worth the extra cost to insure against this accident it might be prevented by insulating the dynamo itself from earth, but connecting again to earth through a small current cut-out, which, by the fact of its acting, would indicate a fault on the armature to the frame.

Will you permit me a further trespass on your space, to add that the object of my note on the "transformer" effect in shunt-wound dynamos in parallel was—(1) to call attention to the fact that *any* short-circuit in the armature coils (not to earth) of such a machine, even when disconnected from the bars, *must* produce through its shunt-circuit, if this is connected to the bars, a *drop* of voltage across them, and that it is conceivable that even a reversal of polarity may be caused ; and (2) to show that, due to the same causes, a short on the bars, if all the machines are not working at precisely the same portion of the B and H curve, may cause some to motor, thus throwing a doubly heavy load on the remaining dynamos.

I have heard it stated that a *sudden* increase of load on the 'bus-bars fed by shunt-wound dynamos in parallel, even when they are direct-coupled to engines governed for constant speed, has been known to cause the machines to drop their volts and cease to excite ; whilst if the same load were gradually put on it would be taken up by the machines quite satisfactorily. Is any well authenticated case of this nature known ? I do not see how (if it exists) it can be explained except upon the supposition that the "transformer" effect in No. 1 machine has been greater than in the other, and has thus reduced the field of No. 2, causing it to motor, and has had all the outside load and the motoring load thrown upon itself, thus actuating its maximum cut-out.—Yours, &c.,

Bristol, Dec. 3. ARNOLD PHILIP.

PROF. WILSON'S "ELECTRIC TRACTION."

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Your review on the above book hardly seems to me to be fair, and seems to be more of a personal attack on Prof. Wilson than a criticism of his book.

To begin with, the statement that "it bears throughout the evidence of the hand that has had little or no practical experience of its subject matter" is totally untrue. It is well known that Prof. Wilson is one of the professors who *has* had practical experience both here and abroad, who has been through the shops, and was responsible, when in Messrs. Siemens' works, for the design of some of the largest dynamo-electric machines both for traction and lighting.

Then take your reviewer's remarks on the tests of storage cells. It seems to me that Prof. Wilson took probably the two best known types as representative of what one might expect from cells with heavy rates of discharge ; and, considering the important part storage cells are likely to play in the propulsion of vehicles by electricity, these tests, coming from an impartial person, are, I think, most useful and welcome, and I should have thought the curves were quite sufficient summing up of the results.

If your reviewer will refer to the article by Prof. Wilson in your issue of Oct. 11, 1895, on the "Heating of Dynamos," he will see that Prof. Wilson was quite aware that the losses due to eddy currents and hysteresis are *not* constant, and he does not say they are : he even goes so far as to print the word "*assume*" in italics, thereby calling attention to the fact that the assumption is not correct, but suffices for the purpose he had in view.

Then, with regard to your remarks as to why the second shoe is required, I maintain that Prof. Wilson is perfectly correct. The series or main circuit coils, as Prof. Wilson states, would only be called upon to give a small augmentation of the induction ; and if the shunt circuit were not broken at all, I fail to see how the magnets can lose their magnetism.

Regarding the next so-called "error." On p. 188, Prof. Wilson certainly states that the generators at Dublin, "at 600 revolutions per minute give from 2,300 to 2,500 volts," but he does not state (as you say) that they give *only* this voltage ; and when discussing the efficiency of the system of conductors he does so on the maximum P.D. which the Board of Trade allow them to use, *i.e.*, 3,000 volts ; and this is surely the fairest way of treating it.

Then as to whom the book was written for. It certainly seems to me to fill the gap between the elementary treatises dealing with the principles of the sciences and the special advanced technological works ; and this was the object of the book (see publishers' advertisement of their "Science Manuals").

The concluding paragraph is hardly worth commenting upon ; the expressions referred to may not be strictly correct, but are perfectly intelligible. I wonder if your reviewer "shudders" at his own English in the review (see last paragraph but one).—Yours, &c., J. R. SALTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I trust that but few of your readers will so misinterpret the review of Prof. Wilson's book as to consider it rather a personal attack on the author than a criticism of the work itself. Certainly nothing was further from my intention than the introduction of anything of a personal nature : the review was simply the result of a careful and unbiassed perusal of the work in question, and should the author in the future bring forth a more worthy production no one will give it a more kindly reception than myself.

In answer to the criticisms of your correspondent, I may say that when I wrote the review I was not ignorant of Prof. Wilson's career and status ; but I must point out that the fact of having designed dynamos, even at Messrs. Siemens, does not necessarily qualify one to write on the design and equipment of complete traction systems.

Secondly, with regard to the tests of storage cells, I think I am justified in still adhering to my opinion that in a comparatively small work it shows a lack of the sense of proportion to give several pages of tabulated figures of two single types of cell. Even granting that the tables are of interest, they should have been published elsewhere than in the book in question. Nor, if the figures must be given, can the tables and bare curves be considered sufficient without anything to indicate the bearing of the results obtained.

Again, it is but cold comfort for the reader to afterwards learn that the author has elsewhere shown that he understands the variations of eddy-current and hysteresis losses ; he would much prefer that this knowledge should be displayed in the work before him. In this case but few words would have sufficed for this.

An author may, of course, use the word "assume," even in italics, but before doing so he should first make quite sure that the assumption involved *is* sufficiently accurate for the purpose he has in hand.

Regarding the breaking of the circuit, the author's language would lead one to suppose that in some way the shunt circuit itself was actually broken, which, of course, is not the case.

Lastly, people when speaking of dynamos of 2,300 or 2,500 volts do not *say* that they only give that voltage ; but they mean it, and expect others to so understand them. A dynamo may be run to give only 10 volts, but if it is generally employed at 3,000 volts we say that it gives 3,000 volts, and leave it to be inferred that it can also give lower pressures.—Yours, &c.,

THE REVIEWER.

LEGAL INTELLIGENCE.

Savory v. Edward Lloyd (Limited).

An action was commenced on Wednesday before Mr. Justice Day and a special jury, in the High Court, in which Sir Joseph Savory sued Messrs. Edward Lloyd (Limited) and Mr. W. J. Richardson for damages for libel. The defendants are the proprietors and the printer of *London*, and the plaintiff complained that on June 30 last defendants falsely and maliciously printed and published a libellous statement concerning him. In commenting upon a statement made at a meeting of the Common Council of the City of London, by Mr. Brooke-Hitching (also of Marylebone), relating to the circumstances under which the City of London Electric Lighting Co. was established, *London* referred to that transaction as a very discreditable one, combining the characteristics of Hooleyism and Tammanyism, asserting at the same time that certain members of the Corporation were interested in the Pioneer Company, which promoted the present Company, and that the plaintiff, Sir Joseph Savory, the then Lord Mayor of London, was beneficially interested in the promotion. "It is one (continued the journal) of the worst jobs which have tarnished the municipal history of the City of London." After reviewing the history of electric lighting matters generally so far as they relate to the City, the plaintiff and his family connections are charged with having a considerable monetary interest in the City of London Pioneer Electric Lighting Co. (Limited), which, in its turn, promoted the present City of London Electric Lighting Co. (Limited). The journal continued :—"The Lord Mayor for the time being, Sir Joseph Savory, was chairman of the promoting company. He was also a member of the Streets committee, who executed the electric lighting contracts for the Commission of Sewers. Lord Mayor Savory was interested in the company which financed the promoting company—started solely for the purpose of making money out of the interest which the Commissioners of Sewers created and of the contracts which it had granted, presumably in the public interest. What would be thought of members of the County Council were they to degrade themselves to such sordid financial scheming for their own enrichment and the public loss? What would be said if the members of the Highways committee of the County Council promoted a little syndicate to acquire a valuable tramway concession, which in a public capacity they had granted, and then sold to another company, pocketing handsome premiums for their services? The worst feature of the whole business is that one of the chief persons concerned was the Lord Mayor (Sir Joseph Savory), whose official position is fully described in the share lists of the companies. What do the citizens, who all suffer now from the transactions, by excessive electric lighting charges, think of these doings? The Corporation is committed to protect the company against competition, while that company is able to enter the field of rivals in Southwark from its protected centre in the City. Were purchase proposed, the stock of the company would immediately rise in value." Plaintiff alleged that the defendants meant thereby that plaintiff had abused his official position, and had sacrificed the public interests for the purpose of making private gain, and had been guilty of discreditable, corrupt and dishonest conduct unfitting him for any official position in the City of London.

Defendants pleaded that the words did not mean what was alleged by plaintiff, and that they were incapable of any defamatory meaning. They further pleaded that, in so far as the words consisted of allegations of fact, they were true in substance and in fact; in so far as they consisted of expressions of opinion, that they were fair comments made in good faith and without malice upon the said facts, which were matters of public interest.

Sir E. CLARKE, Q.C., for the plaintiff, said that his client was an alderman, and had long been connected with the City. Prior to becoming Lord Mayor in 1890 he was not a member of the Common Council, nor was he, prior to that time, connected with the Commissioners of Sewers. The justification pleaded by defendants was founded upon mis-statements of facts relating to the plaintiff's position. From 1878 to 1890 the Commissioners of Sewers were the lighting body in the City. The plaintiff had nothing to do with the electric lighting in the City. The contracts for that purpose were made in 1890 before the plaintiff was appointed Lord Mayor. When elected Lord Mayor plaintiff made a statement as to the companies with which he was connected. In consequence of representations made to the plaintiff and under great pressure, the plaintiff joined the City of London Pioneer Electric Lighting Co. This was done publicly and under public pressure. He took shares in the company, as a matter of duty, to the extent of £1,250. The Pioneer Company, having fulfilled its duty, was wound up, and the plaintiff made a profit on his shares to the extent of £625. This was all that plaintiff had to do with electric lighting. All that plaintiff did was in the public interest and to promote electric lighting.

Sir J. SAVORY said he had nothing whatever to do with the contracts entered into with the Brush Co. or the Laing, Wharton and Down Co. In 1891 he was approached by a deputation, and he was asked whether he would join a company to carry out the electric lighting work. He at first declined, but ultimately on great pressure agreed to become chairman of the Pioneer Co., which was to carry out the work. He thought it his duty to do so as Lord Mayor. One of the objects of the company was to tide over the period until a larger company could be formed. The City of London Electric Lighting Co. was formed, and as the Pioneer Co. had performed its duty it was voluntarily wound up. He did not become chairman of the new company, though he was asked to. The Commissioners of Sewers entered into a contract with the Brush Co. and Laing, Wharton and Down. The Electric and General Investment Co. promoted the City of London Electric Lighting Pioneer Co. He did not know that every one of the companies made a profit. At one time he had shares in the Brush Company. The chairman of the company, Mr. J. B. Braithwaite, was his cousin. When he became chairman of the Pioneer Company he did not investigate the contracts. As to the Electric and General Investment Co., he got one Founders' share and 100 Ordinary. He held them for about a year. He got £129 for the Founders' share, and for the Ordinary shares £198. 14s. 6d. The reason of the promotion of the Pioneer Company was that during the Baring crisis the Brush and the L.W. and D. Companies had a great difficulty in finding the necessary capital by Feb. 7, 1891, and if they failed in this the contracts with the Commissioners would have lapsed. The Pioneer Company was not really the Electric and General Investment Co. in another form. The total capital of the Pioneer Company was £100,000, £50,000 only being called up. The secretary of the Electric and General Co. was also the secretary of the Pioneer Company. Every shareholder in the Pioneer Company got 50 per cent. profit for the few months it was in existence. It was an advantageous thing for the City that a virtual monopoly should be granted to one company. He did not know that it was in the teeth of the Electric Lighting Act, 1880. He did not know that before the prospectus of the City of London Electric Lighting Co. was brought out the Pioneer Company had entered into contracts with the Brush and L. W. and D. Companies to give them the work in their districts for £300,000 and £200,000 respectively. There was an agreement between the Pioneer Company and the Brush Co., but he could not say how the figures in that contract were fixed. He denied that a considerable sum of money was given to the Brush and L. W. and D. Companies to transfer the monopolies created by the Commissioners of Sewers. If he had known it, he should, as Lord Mayor, have thought it a discreditable thing. He did not believe a penny was given. He did not know that the L. W. and D. Co. paid the Electric and General Investment Co. £10,000. He could not say why the L. W. and D. Co. was to pay the Investment Co. £9,000. He did not know why the Brush Co. was to pay to the Investment Co. the sums of £1,000, £9,000 and £5,000. He did not know that the capital of £1,200,000 of the City of London Electric Light Co. was now worth £2,400,000 on the Stock Exchange. He had 200 Ordinary shares and 1,000 Preference. He made £200 or £300 profit on them. It was untrue that the Pioneer Company was a promoting company to buy up the two competing companies and create a monopoly. The Pioneer Company never carried on the business of an electric lighting company. It wound-up directly its mission was accomplished. He never inquired if the Electrical and General Investment Co. paid 30 per cent. He did not know that there was a division amongst the Commissioners of Sewers as to whether the Pioneer Company should be allowed to go on. He did not know that the Commission of Sewers required an undertaking that nothing should be paid to the contractors for the transfer of the monopoly. Instead of £150,000, the City of London Electric Lighting Co. paid the Pioneer Company £75,000. He was not aware that the Council had been advised that they would be bound to oppose any other provisional order for electric lighting. All the companies were publicly advertised. He was not personally aware that his family were shareholders. He believed that the contracts were absolutely beneficial to the City of London. If the contracts had lapsed, electric lighting in the City would have been indefinitely postponed. He believed that the contract with the Brush Company provided most carefully and scrupulously for the work being properly carried out.

Major-General WEBBER, C.B., said he was formerly consulting engineer to the Brush Company, and frequently consulted with the Commissioners of Sewers. Ultimately, in May, 1890, a contract was entered into for public lighting. The Pioneer Company entered into a contract with the Brush Company to do certain works at a certain price. The specification of works was prepared under his instructions. In 1890 he thought it would be better if municipalities did the work themselves, but he knew no municipality would do the work. It was considered a great risk financially and no municipality would saddle the ratepayers with such a rate. The cost of providing London with electric light would be far greater than that of any other city. He had been consulting engineer to the Brush, Pioneer, and City of London Electric Lighting Companies. The Brush Company could not expediently raise capital for the purpose of its contract. The figures of £300,000 and £200,000 were fixed after consulting with him, but he could not refer to any document showing how they were made up. Capital cost regulated the price charged for electric light, and the extra capital cost in London explained the difference in charges between London and other places.

Mr. W. H. PREECE stated that he had been connected with the Post Office since 1870. He had been permitted to advise local bodies with regard to electrical matters, and especially the City. He was originally consulted with respect to electric lighting in the City as early as 1882. From 1882 to 1890, when contracts were entered into, he was in constant communication with the representatives of the City. He made various reports to the Commissioners of Sewers, who consistently acted on the advice of Col. Haywood and himself. The Streets Committee of the Commissioners of Sewers took a great deal of trouble and spent considerable sums of money in their endeavour to secure contracts for the electric lighting of the City. In 1885, the expenditure of the Corporation in this way had amounted to many thousands. In 1889 the City was mapped out into three districts—east, west and central—with a view of securing the best arrangements for lighting the City, and he prepared specifications. Several companies, including the Brush and Laing, Wharton and Down, sent in tenders, which were submitted to him and to Col. Haywood, and they made a report upon them, and in consequence the tender of the Brush Company was accepted for two of the districts, and that of Messrs. Laing, Wharton and Down for the third. A provisional order was then applied for, and the circumstances of the case were considered by the Board of Trade. He believed the Corporation acted wisely in entering into the contracts. The contracts were made in May, 1890, but it was not until February

Digitized by Google

1891, the contractors began their work. Sir J. Savory never had anything to do with him in this matter to his recollection, nor did any member of the Corporation or of the Streets committee attempt to influence him. The City of London was a most difficult district to supply with the electric light, and, consequently, the cost of supplying it was more expensive than that of northern towns. He had nothing to do with the financial parts of the contracts. In 1889 he made a report to the Corporation that he was in favour of potential competition, instead of having one company. He thought there would be an advantage in having three companies, as such an arrangement would encourage a spirit of emulation. He thought the financial position of both companies was good. He never contemplated that a contract would be given to a company not then in existence. In his opinion the transference of the contracts to a large and wealthy company would enable the undertakings to be more economically managed.

Mr. H. MONTAGUE BATES (clerk to the Public Health Department of the Corporation) said he was clerk to the late Commissioners of Sewers, and remembered the discussions with reference to the lighting of the City by electricity, but the plaintiff took no part in them. The second contract with the Brush Company was signed on Feb. 5, 1891, the day on which the Pioneer Company came out. The City authorities were not consulted at the transfer of the contract until after it had taken place. The late law officer of the Corporation had been asked to report as to the power of the Corporation to establish a competitive supply; but he could not say that he had reported to the effect that the Corporation had no power to enter into competition with the existing company. The transfer to the new company was permitted on the understanding that the rights of the Commissioners and of the ratepayers were not prejudiced. Plaintiff had nothing whatever to do with the discussion on the question of electric lighting, and certainly made no attempt to influence the decision of the Commisioners of Sewers.

Mr. J. B. BRAITHWAITE, jun., said he was a cousin of the plaintiff, who had a brother in his firm. Plaintiff had nothing to do with the subscriptions to the different companies by the members of his family. They acted as other customers did, on the recommendation of his (witness's) firm. He was one of the directors of the Brush Company. In 1890 it was extremely difficult for money to be raised for the purpose of lighting the City by electricity. In consequence of the Baring crisis it was quite impossible to obtain capital. The Brush Company received money for work it had done, but nothing in the way of a bonus. The promotion of the Pioneer Company was a necessity in consequence of the Baring crisis. It was estimated that the works under the Corporation contract would cost £1,200,000.

Mr. CARSON, Q.C. (for defendants): Why could not the Electric and Investment Company finance the work?—Because it was impossible to raise £1,200,000 at that time. Why could not the Electric and Investment Company do what the Pioneer did?—The risk was too great. The money subscribed by the Pioneer Company would have been hopelessly lost if this company had not been floated.

Was the Duke of Marlborough a director of the Brush Company, the Electric and General Investment Co., and of the Pioneer Company?—Yes.

The further hearing was adjourned till to-day (Friday).

Christoffer and Others v. the National Telephone Co. (Limited).

This case came before Mr. Justice Lawrence and a Special Jury on the 2nd inst.

Mr. MOYSES, for Messrs. J. C. and G. J. Christoffer, said they were the trustees under the will of the late Mr. Christoffer, owner of the property in respect of which the action was brought, Mr. Wm. Barrett being the occupier of the property. The action was brought to recover damages for trespass committed by the defendant company extending over 14 years, and which had existed unknown to the plaintiffs, as they were under the impression that the company, being termed "National," had something to do with the State, and had a right to do what they had done. It was only at the beginning of the present year that the plaintiffs became aware of their rights, and the writ in the action was issued on April 13. The facts were that no less than 546 wires on strands or cables passed over the plaintiffs' house in Assam-street, Whitechapel. At the back of the house there were two large poles, which were put into the ground to the depth of over 6ft., one pole being put there 14 years ago and one seven years ago. One pole was only about 12in. from the back wall of the house in question, and the other about 40in. These poles were subject to oscillation during the wintry weather, and had a pernicious effect on the adjoining property. Three years after the first pole was put there, there appeared a rent in the wall. That rent had been stopped up two or three times, but it had reappeared again and other mischief had been done. One of the plaintiffs caused a letter to be written to the defendants asking for compensation for the wires passing over the property, but the defendants replied denying liability. Hence the present action.

Plaintiffs gave evidence as to the damage done, and the annoyance to the occupiers by the noise of the wires.

Mrs. BARRETT, who had lived in the house 11 years, said the crack in the walls appeared after the poles were put there. She had then complained to the landlord as to the nuisance caused by the wires. The wall had given way and a ceiling had come down; also some of the doors would not close.

Mr. FARTHING, architect and surveyor, said he estimated the damage done at £45. It was caused by the oscillation of the poles.

Mr. HITCHCOCK, surveyor and engineer to the Vestry of St. George's, Southwark, gave similar evidence.

Mr. ROSKILL, for defendants, said that he would call evidence to show that the cracks were in the wall 14 years ago, and were much the same now as they then were.

Mr. L. H. ISAACS, surveyor to the Holborn District Board of Works, gave evidence that the poles had nothing to do with the cracks in the wall and that the difficulty as to the doors not closing was due to subsidence.

Mr. W. R. DEANE, architect, said that his opinion was that the cracks were caused by settlement or subsidence.

The jury awarded the owners of the property £45 and the occupier £5 damages. Judgment accordingly.

Holliday v. National Telephone Co. (Limited).

On Monday, in the Court of Appeal, Lords Justices A. L. Smith, Rigby and Collins heard an appeal from the order of Mr. Justice Wills and Mr. Justice Lawrence, reversing the decision of the Deputy Judge of the City of London Court, who found for the plaintiff for £25. The previous proceedings were fully reported in our last issue, p. 202. The present application was granted.

Alwyn and Craven v. G. Straus and Co. (Limited).

In the City of London Court last week, before Mr. Registrar Wild, plaintiffs sued defendants to recover the price of a number of incandescent electric lamps which they had supplied, and which were alleged to give a bad light. A member of plaintiff firm said the lamps supplied were used in an electric light installation at Parr's Bank, Kensington. In consequence of complaints, the lamps had to be taken down, and fresh lamps substituted. Defendants had been asked to return the price of the lamps, or to exchange them. They refused, because of the delay in making complaint. One parcel of lamps was purchased in May, and were used with others that were ordered in August. They were not fitted until September, and complaint was made in October. The lamps were of the high-voltage type, and could not be tested on an ordinary circuit. Defendants urged that the reason for refusing to exchange the lamps was that there had been a delay of five months before complaint was made. The Registrar was of opinion, from the evidence before him, that the lamps would not give a proper light, and he considered they were absolutely useless. He thought, under the particular circumstances, that complaints were made in a reasonable time, and plaintiffs were entitled to recover. Judgment for plaintiffs for £1. 3s. 3d., and costs, the lamps to be returned to the defendants.

Sun Insurance Co. and Another v. the Corporation of Dublin.

At Dublin, before Mr. Swifte, magistrate of the Southern Police Court, the Sun Fire and Life Insurance Co. summoned the Corporation of Dublin for that they "on Nov. 21, 1898, and on the two following days, at 17, St. Andrew-street, made default, and have continued to make default, in supplying energy to the complainants, being the occupiers of premises at 17, St. Andrew-street, to whom they were required to supply such energy under the provisions of the Dublin Electric Lighting Order, 1892, and thereby rendered themselves liable to a penalty not exceeding £2 in respect of every such default for each day on which such default occurred." The Corporation were also summoned by Wilfred Fitzgerald, of the same place, for similar default.

Mr. O'SHAUGHNESSY, for the Corporation, said that under the Act no penalty was incurred by the Corporation where the default to supply the energy was due to unavoidable circumstances. This case was not one of two or three 40s. penalties, but it meant a tremendous liability, for these were pioneer cases. A cable was laid down which was defective, with the result that the electric service broke down. That cable at the time it was laid was the best then known, and it was believed that it would be good for 25 years. Electrical science was yet only in its infancy [!], and this breakdown could not be foreseen. The Corporation were now engaged putting down a new cable at a cost of £100,000. The default was admitted, but they denied wilful or negligent default and he would prove that the breakdown was unavoidable and could not have been foreseen.

Mr. RUDDLE, electrical engineer to the Corporation, deposed that he had supervised the laying down of the original cable, under the consulting engineer, in 1891. That cable, the upper cable, was then known as the best on the market. It gave satisfaction for four years. They then discovered that, by some unaccountable chemical or other action, the rubber insulation was destroyed, with the result that the current leaked and was lost, and sometimes the supply was stopped. They had to open the streets to discover the cause. The Corporation in July began laying down a new cable which was guaranteed to last 10 years. The men were still at work on the laying of the cable, which was being put down as rapidly as was consistent with safety. In November there was a breakdown in the rubber of the cable, which it was impossible to guard against. There was no valid explanation yet given of this. The Board of Trade regulatious obliged them to test the cables once a week, but they tested them twice daily. On Nov. 21, when the cable in St. Andrew-street was tested, it was all right, but in the evening the test showed that it had broken down. The transformer on these premises was spoiled by the rain getting into the transformer chamber. The transformer could not be repaired in wet weather without danger to the life of the operator. The transformer could be repaired when the current was cut off. They would not repair it until the cable was first set right.

Mr. SHIEL, for the prosecution, said that the failure to supply current which left these premises in darkness was due to the breakdown of the defendants' plant, which they should have guarded against.

Mr. O'SHAUGHNESSY contended that the Corporation were not liable when every precaution had been taken that was possible.

The MAGISTRATE said that the engineer's evidence showed that this was an unavoidable accident. Electricity was yet more or less in a tentative position, and at the time the cable was laid down the Corporation took every possible precaution to get the best they could. It might be a fair case for investigation, but he should dismiss the summons, giving, however no costs

Stegmann v. Williams.

This case came before Mr. Justice Grantham on Wednesday, on an application by plaintiff, an electrical engineer, to recover the price of electrical appliances and electric light fittings supplied—£18. 17s. 6d., £2. 17s. 6d., and £8. 10s. for an electric sign for the Savoy Palace Hotel. There was no defence, and judgment was entered for plaintiff for the amount (£80. 5s.) and costs.

Cambridge Electric Supply Co. (Ltd.) v. Cambridge Union.

At Cambridge on Friday, the Deputy Recorder delivered judgment in the appeal of the Cambridge Electric Supply Co. against the assessment of the overseers of Cambridge. Particulars of this case appeared in our issues of 8th Oct. and 4th Nov. The Deputy Recorder now said he had been deputed by the Recorder to deliver his judgment, which was for the respondents, and he dismissed the appeal with costs.
